Elicitation of parameters from fishers. Interviews treatment and integral text

Scoring

The interview notes were reviewed to identify quantitative scores applying following criteria (in this ordered):

- *C1 (score available)*: When a clear and unique self-declared score was provided, this was used as a score. In case the interviewee provided two scores (e.g.: 4 or 5), it was used the average (4.5). For those answers were alternative were provided for gear/target, create separate scoring.
- *C2 (score to be interpreted)*: Answers that were providing meaningful text but not a clear number, or that were considered worth of further attention, were scored as 999.
- *C3 (does not apply)*: Answers that were missing because the event/condition does not apply were scored as -999. When the “does not apply” was identified in more than 50% of the answers, the combination of fishing style-event was excluded from further analysis.
- *C4 (can't answer)*: Answers that were missing because people did not have a personal experience to refer but refers to an event that is relevant (i.e.: if during a storm you never go out, you might don't know about how catchability changes) were scored as -998.
- *C5 (garbled)*: Answers that were not coherent with the question were scored -997

Table S.1: coding system used to categorise answers according to their interpretation

Score	Type	Description
x	C 1	Number (x) available
999	C 2	To be interpreted
-999	C 3	Does not apply
-998	C 4	Cant answer
-997	C 5	Garbled

The questionnaires originated more than 500 scores. Of these, 267 enabled clear quantitative scoring, whereas 105 answers indicated clear information but no quantitative score and required interpretation. A total of 158 answers indicated that the combination of extreme events and questions was not relevant (123) for that question or there was not enough information to answer (35). Only 5 answers were considered incoherent with the question (e.g.: Supplementary Table A.165), and these were excluded from the analysis.

Table S.2: number of answers by interpretation category

Score	Frequency
x	274
-999	118
999	102
-998	38
-997	4

Interpretation

A structured coding approach was applied to those answers scored as 999 using both human expertise and artificial intelligence assistance.

- Text for unclear answers was revised to extract the main keywords (i.e.: most people say; I think it does not affect so much etc.), and to identify whether the answer was needed to support narrative or to provide quantitative information.
- The keywords were pooled based on the expected type of answer (e.g.:). Three researchers independently assigned quantitative scores to textual descriptions based on predefined LIKERT scale. These expert based ratings were averaged to create a consensus dataset, which was used to establish interpretive patterns linking descriptive terms to quantitative values.
- Answers without keywords needed for quantitative information were reviewed with Artificial Intelligence. We employed OpenAI’s GPT-5 (ChatGPT, September 2025 version) as an assistant to generalize these patterns to new responses. The model was not trained on external data but was guided by the team’s own scoring framework. For each new description, the model produced a suggested numerical score along with a written rationale. All outputs were reviewed and validated by the researchers to ensure consistency with the established coding scheme
- Answers without keywords that were needed to support narrative (i.e.: management) were left unscored.

Expert scoring

Expert scoring of keywords produced the following results, which were used to assign scores to 87 answers:

Table S.3: scores assigned by experts to answers not providing an explicit scoring

question	coding	answer	Exp1	Exp2	Exp3	mean	sd
is it possible [to avoid something]	1-5; from 1 – very difficult, to 5 – very easy	hard	2	2	2	2	0.0

How much concern for your personal safety	0-2; 0 – no concern, 1 – personal injuries, 2 – life-threatening	big concern	no info bc difference between 1 & 2 is type of concern, not level alone	2	2	2	0.0
How much concern for your personal safety	0-2; 0 – no concern, 1 – personal injuries, 2 – life-threatening	some risk	no info bc difference between 1 & 2 is type of concern, not level alone	1	1	1	0.0
How much concern for your personal safety	0-2; 0 – no concern, 1 – personal injuries, 2 – life-threatening	worrisome	no info bc difference between 1 & 2 is type of concern, not level alone	1	1	1	0.0
does [something] allows you to change location	0-2; 0 – no, requires that I am at the same place, 1 – yes, to some extent, 2 – yes, much that makes great mobility possible	sometimes, but not always	1	1	1	1	0.0
does [something] allows you to change location	0-2; 0 – no, requires that I am at the same place, 1 – yes, to some extent, 2 – yes, much that makes great mobility possible	it allows a lot of freedom	2	2	2	2	0.0

AI scoring

This option was applied to a limited number of responses.

Q1

Question: How much do you think they vary among the group of people you represent? Possible answers: 1–5; from 1 – not at all, to 5 – very much

Observed Answer: it is so personal, some do not care at all, they just drink beer all day; we discuss things like this all the time, most are probably quite stressed by such situations

Score: 4

Why: The reply indicates clear heterogeneity — a minority who “do not care at all” vs a majority who are “quite stressed.” That is meaningful variation but phrased so that most are similar (stressed) with a minority different. In your training examples, minority exceptions vs majority agreement tended to map to a high-but-not-maximum value. Confidence: medium–high.

Q2

Question: How much do you think they vary among the group of people you represent? Possible answers: 1–5; from 1 – not at all, to 5 – very much

Observed Answer: There are some who have rights but don’t practice at all, and then some who practice like I do, just now and then. Then there are those who have leased out their permits, and in those cases, there is somebody who practices quite intensively

Score: 5

Why: The answer describes the full spectrum (no practice → occasional → very intensive). That explicit broad distribution matches your examples that consistently received top-end variability scores. Confidence: high. Q2 Question: How likely is it that you explore new techniques or strategies? Possible answers: [1–5; from 1 – very unlikely, to 5 – very likely] *Observed Answer:* Would probably try to find solutions; activity would certainly change, and then people would follow that change; there is probably some variation among people depending on what one is specialized in *Score:* 4 *Why:* The speaker says they “would probably try” and expects change and follow-up by others — language that in your dataset equates to a positive likelihood but not the absolute “definitely” (which you typically scored a 5). The note about variation reduces absolute certainty slightly. Confidence: medium–high.

Q3

Question: If your income from activity A decreases, can you complement or replace it? Possible answers: [1–5; from 1 – very unlikely, to 5 – very likely]

Observed Answer: It would be very hard to replace activity A it with other income. Most have other jobs in winter, but A is such a significant part of income

Score: 1

Why: The phrase “very hard to replace” and “A is such a significant part” matches wording in your dataset that mapped to the low end (very unlikely) — even though there are seasonal other jobs, the respondent explicitly indicates replacement is essentially not feasible. Confidence: high.

Q4

Question: How easy is it to avoid an extreme weather event by going to another location?

Possible answers: [1–5; from 1 – very difficult to avoid, to 5 – very easy to avoid] *Observed Answer:* I Stop my activity *Score:* 1 *Why:* The respondent says they stop the activity instead of relocating to avoid the event — that implies relocation is not used/feasible. In your training set, answers that indicate “we don’t/stop” were scored at the difficult end (1). Confidence: medium — short reply is slightly ambiguous about whether “stop” means temporarily pause or that relocation is impossible, but both interpretations point to very low ease of avoiding by moving.

Q5 *Question:* If the following type of extreme event occurs, how likely is it that you go out and do the activity? Possible answers: [1–5; from 1 – very unlikely, to 5 – very likely] *Observed Answer:* we wait because the product can spoil *Score:* 1 *Why:* “We wait” because of spoilage risk indicates they do not go out during the event — i.e., very unlikely. In your dataset, similar phrasing (“we wait / won’t go because...”) mapped to the lowest likelihood. *Confidence:* high.

-997	C 5	Garbled

Interviewee: I 1

focused on the waters around stockholm, both in the archipelago and in lakes. he guides mainly for trout, pike, and perch, and makes a living from his business. on average, they guide about 100 days per year. the guiding business is seasonal and follows the fishâ€™s behaviour, activity, and migrations. they fish in lakes, streams and coastal areas. they can use boats in coastal areas and lakes. it is more common in spring and summer. in winter they guide ice fishing. if there is no ice they can switch to spinning but this is unpredictable. the most fished species are sea trout, salmon, pike, and perch. they primarily practice catch and release fishing. because fishing guide is mostly a touristic activity, it is more active in the weekend, and their flexibility is linked to customers flexibility. how they adapt: fishing guide adapts all the time according to the conditions and the clients need. they are flexible for place, species and gear, but its ability to adapt to conditions depends on clientâ€™s flexibility. he notices a decline in demand during extreme hot weather, and for security reason he cannot guide if he feels danger. in winter he can replace ice fishing with spinning but cannot book this in advance. in summer he can choose between different options depending on the conditions. he can change fish location and target (and accordingly gear) in heatwaves, algal bloom and stormy conditions. in hw he can move the trips to mornings and evenings. in hw and ab he moves from shallow waters for pike to below the thermocline for sea trout; in stormy conditions he goes the other way around.

Q 2 - go_fishing

If the following type of extreme event occurs, how likely is it that you go out and fish?

[1-5; from 1 – very unlikely, to 5 – very likely]

Table S.5: Interviewee: I 1 Q 2

	Event	Answer	Score
a	Heatwave in the winter season	Very different, depends on what is booked. Sometimes ice fishing is booked and then we have to cancel all bookings, sometimes open water fishing is possible. Lose ice fishing customers and gain spin fishing ones; 1 ice fishing (spin fishing customers can't be booked in advance in winter, you can't count on a heatwave in winter)	NA
b	Heatwave in the summer season	4. Some fishing is closed if it gets too hot, e.g., river fishing. It's difficult to fish if it gets extremely hot, but I try to adapt; so far I haven't canceled coastal fishing, I move it to mornings & evenings. But, for example, Nyköpingsån was closed because the water was too warm. Also depends on how hot it is. It happened in 2018, depends on what happens with our fish	4

c	Severe icing (in the winter season)	1. Haven't experienced severe icing, only seen it on YouTube; don't know if it happens on sportfishing boats; it has to be safe, not dangerous; if it's icing like on the Great Lakes, then the boat breaks	1
d	Algal bloom (in the summer season)	1. Usually happens offshore; can't handle it if I have a trip, e.g., from Sandhamn, but then we can go inland when there's algal bloom	1
e	Extreme cloudburst (in the summer season)	1, dangerous	1
f	Gale	5Gale is normal (sometimes we cancel), from strong gale and upwards we stay home (18 19 m/s average and 25 m/s in gusts is not possible)	5
g	Storm	1	1
h	Are there any of these in combination that affect how likely it is that you go out and fish?	A lot is about safety, combinations become dangerous, e.g., strong icing and strong winds, I avoid this as much as possible; would also get fewer requests, since fishing should be enjoyable	NA

Multiple options identified

Table S.6: Interviewee: I 1 Q 2

	Event	gear	Score (given)
a	Heatwave in the winter season	ice fishing	1
a	Heatwave in the winter season	rod	5

Q 3 - catchability

Do you experience that the catchability of the fish changes due to such extreme weather events?

[1-5; from 1 – much worse, 3 – no difference, to 5 – much better]

Table S.7: Interviewee: I 1 Q 3

	Event	Answer	Score
a	Heatwave in the winter season	1 ice fishing, there is no catchability if there are no fish; however, the fish like when it gets warmer, so if it's spin fishing then 5	NA
b	Heatwave in the summer season	2	2
c	Severe icing (in the winter season)	No, can't conduct fishing; if it is possible to fish then it becomes 2.	2
d	Algal bloom (in the summer season)	2, the fish move from that area; also becomes difficult fishing (fished during an algal bloom this summer, had to go all the way into the bay because where we intended to fish we only got weeds on the hook).	2

e	Extreme cloudburst (in the summer season)	Don't go out in cloudbursts; fish react to pressure changes; if there is low pressure during a downpour, then they stop biting, but if it rises after the downpour then it can be good; so I can't say	-998
f	Gale	: 2, a gale doesn't matter for the fishing itself, other than that the gear is hard to use	2
g	Storm	Don't go out in a storm	-998

Multiple options identified

Table S.8: Interviewee: I 1 Q 3

	Event	gear	Score (given)
a	Heatwave in the winter season	ice fishing	1
a	Heatwave in the winter season	rod	5

Q 4 - catch_assemblage

Do you catch a different composition of species during such extreme weather events?

[1-5; from 1 – very similar, to 5 – very different species composition]

Table S.9: Interviewee: I 1 Q 4

	Event	Answer	Score
a	Heatwave in the winter season	: 5 sea trout on open water, instead of perch and pike under the ice	-997
b	Heatwave in the summer season	: 5 redirect the fishing down below the thermocline	-997
c	Severe icing (in the winter season)	No information	-998
d	Algal bloom (in the summer season)	More about changing location (deeper), 5 choose other species (we fish pike & perch, sea trout)	-997
e	Extreme cloudburst (in the summer season)	No other species, more that we don't fish	-998
f	Gale	: 2 sometimes; if it blows too hard and we are supposed to fish trout, then sometimes we have to go in and fish perch & pike instead	2
g	Storm	Cancel	-998

Q 5 - catch_condition

Are the fish in the catch of worse condition or quality when caught during extreme weather events, compared to under normal weather conditions?

[1-5; from 1 – much worse, 3 – no difference, to 5 – much better quality]

Table S.10: Interviewee: I 1 Q 5

	Event	Answer	Score
a	Heatwave in the winter season	3	3
b	Heatwave in the summer season	2, a b it worse	2
c	Severe icing (in the winter season)	3	3
d	Algal bloom (in the summer season)	2	2
e	Extreme cloudburst (in the summer season)	3	3
f	Gale	3	3
g	Storm	3	3

Q 6 - cope_condition

If the condition/quality of the fish in the catch is negatively affected, how likely is it that you can do something about it? Explain what!

[1–5; from 1 – very unlikely, to 5 – very likely]

We release 98% of the fish; we are more concerned with the survival of the fish, e.g., during a heatwave survival becomes difficult; we don't want to fish pike when it's 30 degrees, then we'd rather fish sea trout that can survive better when we release it, since it goes down to colder depth

Table S.11: Interviewee: I 1 Q 6

	Event	Answer	Score
a	Heatwave in the winter season	NA	-999

Table S.47: Interviewee: I 1 Q 41

Answer	Score - low (given)	Score - up (given)	Unit
I always guide myself; there are some who sometimes take in an extra person; quite expensive, since it is salary and employer's contributions etc. (guess they get 1500 SEK, so in total it becomes 3000 SEK).	2000	3000	sek_day

Q 42 - extra_cleaning_cost

What are the costs for gear cleaning (in case of unusual fouling, e.g., due to algal bloom)?

[free text description]

Table S.48: Interviewee: I 1 Q 42

Answer	Score - low (given)	Score - up (given)	Unit
a whole workday for service, so it costs what I earn on a fishing day; no, not for algal bloom, but in gale or storm there are many lines that must be fixed; twice I have broken the boat due to icing, the trim motor and the steering, 15,000 SEK per time.	NA	NA	sek_day

Q 43 - exytra_other

Are there any other extra costs that may arise during extreme weather events, and how large are they then?

[free text description]

Table S.49: Interviewee: I 1 Q 43

Answer	Score - low (given)	Score - up (given)	Unit
the biggest cost is the loss of income. Cancelled fishing days. A tourist usually does not rebook, especially if it is short notice change then I don't have time to get in something else. Guides for corporate events are at 30,000 SEK, or 60,000 SEK when we are out with 6 boats; if you miss that then the whole income disappears; loss of income also arises because people do not book when there is extreme weather.	NA	NA	sek_day

Q 44 - unc_36_42

How much do you think the answers to these questions (questions 36–43) vary between fishers in the group you represent?

Table S.50: Interviewee: I 1 Q 44

Answer	Score
significant variation; 5.	5

Q 45 - addition

Anything you want to add?

[free text description]

Table S.51: Interviewee: I 1 Q 45

Answer	Score
There may be disease among the fish during heatwaves, and that can have consequences for fishing for five years ahead; and algal bloom we do not know, but it does not feel good. We are completely dependent on the fish being well. How have perch and pike been doing this summer? It was a bit weak when it was hot, but now they have started again. Probably quite a normal year. One adapts to the new. Sour that one cannot fish in the outer archipelago. It is an enormous difference from how it was when I was little, we would need supportive stocking of the pike stocks. First year with protection. I have not seen so much herring in 15 years! We have had incredibly little fish coming in to spawn earlier; when they last did test fishing at Mörkö, there was an 84 86% decline in spawning herring. Out last week, then there was herring in Furusundsleden, a lot of herring, proper schools. Summer herring. Don't know when I last saw that. Very positive! Will have great impact on the predatory fish stocks. Hope that the seals can move out again, so they don't have to hang around	t Slus

Q 46 - substitution_capacity

If I lose one planned fishing day, I can usually make up for it later without it affecting what I achieve overall

[1–5; from 1 – strongly disagree, to 5 – strongly agree]

Table S.52: Interviewee: I 1 Q 46

Answer	Score
The income is gone for that day. You lose customers. Even if you reschedule the fishing day, you lose a new customer on the rescheduled day.	1

Q 47 - unc_46

How much do you think the answers to these questions (question 46) vary between fishers in the group you represent?

Table S.53: Interviewee: I 1 Q 47

Answer	Score
--------	-------

The variation is small between those who guide full-time, everyone would probably agree. If you guide part-time, a lost fishing day doesn't matter that much. So some variation.

Interviewee: I 2

Operates in the north of bothnian bay (kalix). They fish in coastal waters with gillnets and traps (salmon traps and other traps for perch and bream), and they operate from boat at very short distances from their harbour. The target they mention is perch, bream, herring, salmon. They also run vendace fishery for roe production. The main fishing season is summer (from april to august). In winter they generally do not go out until spring comes. they can do sporadically some ice fishing. How they adapt: structured succession of fishing styles within season. depending on the moment, they want to aim for something and may be forced to change. in the case they are fishing with nets (for pike, perch and herring?) they are flexible. their options to avoid hw and ab are to fish deeper, to avoid storms is to choose a different bay. hw especially affects perch, which die immediately. they notice more breams with hw. salmon traps are very rigidly managed and tied to a unique boat. salmon traps do not suffer from hw, but they do of storm, so if they must haul them up with a bigger boat, they get a penalty. vendace season is also rigid and short.

Q 2 - go_fishing

If the following type of extreme event occurs, how likely is it that you go out and fish?

[1-5; from 1 – very unlikely, to 5 – very likely]

Table S.54: Interviewee: I 2 Q 2

	Event	Answer	Score
a	Heatwave in the winter season	Extremely warm winter we ice fish so little, therefore it is a bit difficult to answer. (2)	2
b	Heatwave in the summer season	(3) Depends a little on what we are fishing	3
c	Severe icing (in the winter season)	1	2
d	Algal bloom (in the summer season)	Doesn't affect us much up here; locally there may be algal bloom in a bay. (4)	4
e	Extreme cloudburst (in the summer season)	3	3
f	Gale	1, not me at least with my small boat	1
g	Storm	1	1
h	Are there any of these in combination that affect how likely it is that you go out and fish?	Not really; it's the wind that is decisive for us	NA

Q 3 - catchability

Do you experience that the catchability of the fish changes due to such extreme weather events?

[1–5; from 1 – much worse, 3 – no difference, to 5 – much better]

Table S.55: Interviewee: I 2 Q 3

	Event	Answer	Score
a	Heatwave in the winter season	3	3
b	Heatwave in the summer season	2, Becomes worse, maybe not for all species, but they move to other areas, so you have to search elsewhere	2
c	Severe icing (in the winter season)	Hypothetical question, since we always have ice in winter; icing can happen in autumn, but we rarely fish then, so can't answer that	-998
d	Algal bloom (in the summer season)	Hard to answer, doesn't occur very often	-998
e	Extreme cloudburst (in the summer season)	3	3
f	Gale	It becomes harder to fish, but does not affect the actual catch; (2). Can affect a little since it's harder to fish	2
g	Storm	In a storm you can't fish, so catchability is zero	1

Q 4 - catch_assemblage

Do you catch a different composition of species during such extreme weather events?

[1–5; from 1 – very similar, to 5 – very different species composition]

Table S.56: Interviewee: I 2 Q 4

	Event	Answer	Score
a	Heatwave in the winter season	1	1

Q 36 - fdays

Approximately how many days per year do you fish?

[free text description]

Table S.89: Interviewee: I 2 Q 36

Answer	Score - low (given)	Score - up (given)	Unit
Hard to say. If we have 6 months without ice, we actively fish 1 third of the days. But we keep the gear in the water all ice free days.	50	100	days

Q 37 - income

Approximately how large is your gross income from a fishing day on average?

[free text description]

Table S.90: Interviewee: I 2 Q 37

Answer	Score - low (given)	Score - up (given)	Unit

Impossible to calculate per day. Over 6 months? It's the four weeks of vendace fishing that make up the income. This varies. I haven't broken down exactly what the fishing itself gives, plus there's all the processing afterwards. Then you'd also have to deduct labor costs. Teija calculates roughly to get a value: 1.4 million SEK per year from vendace fishing. Plus some perch and bream. We haven't fished salmon for several seasons — the quota is fished up in 7 days [by those who have good fishing waters near the Torne River], so it's not worth setting the gear, since it takes a week to set and a week to haul.

Q 38 - season_maint

How large are the repair and maintenance costs for the fishing during one year?

[free text description]

Table S.91: Interviewee: I 2 Q 38

Answer	Score - low (given)	Score - up (given)	Unit
I don't remember, it gets lumped together with all other repairs at Guldhaven. We buy 1 boat per season several hundred thousand SEK and a new trawl, 200k SEK, other stuff 100k SEK. Roughly 0.5 million SEK over two years.	1e+05	5e+05	sek_season

How much do you think the answers to these questions (question 46) vary between fishers in the group you represent?

Table S.100: Interviewee: I 2 Q 47

Answer	Score
You will likely get the same reply from both type of fishers	1

Interviewee: I 3

id3 is professional coastal fishermen in southwest bothnian sea (norrsundet). they fish with gillnets and traps. traps are only used for salmons. the main target is herring, whitefish, salmon, perch, and eel. they

also run a restaurant and have several fish trucks. the herring fishing takes place a few hundred meters from the harbor. they mention whitefish, salmon, perch in the local area, and in the gulf of gÅvle. their average distance travel is about 1 hour (assuming 10 knots it is about 20 km) and the longest distance travel is 3 hours (assuming 10 knots it is max 55 km) the main fishing season is summer (from april to august). in winter they generally do not go out until spring comes. how they adapt: id3 can adapt when fishing with nets to hw by avoiding hottest hours, performing shorter sets and using cooling boxes. can also adapt to hw, ab and gales by changing fishing location. to avoid hw and ab they can go further out, the opposite for gales. in any case they can move on short distances and can cope with gales only in shallow waters, they donâ€™t go deep and with storms they donâ€™t go out at all. their spatial mobility is mainly affected by the boat (12m boat) and infrastructure (they want to go back home) on second instance by management that makes possible to fish in proximity (over a coastline spanning of about 60 km in aerial distance). there is not the same flexibility for salmon traps, which are fixed.

Q 2 - go_fishing

If the following type of extreme event occurs, how likely is it that you go out and fish?

[1–5; from 1 – very unlikely, to 5 – very likely]

Table S.101: Interviewee: I 3 Q 2

	Event	Answer	Score
a	Heatwave in the winter season	Depends on ice. Boats are usually hauled up in winter. If forecast shows winter is over, we might launch. Unlikely to put in and haul up again. Might use the small boat if open water, but ice may return. Large boats remain on land. =1 regardless.	-999
b	Heatwave in the summer season	Then we fish, just go further out where it's cooler. =5.	5
c	Severe icing (in the winter season)	5 (icing can happen in spring).	-999
d	Algal bloom (in the summer season)	Rare up here, but still fish. =5.	5
e	Extreme cloudburst (in the summer season)	If gear is already out, we go anyway. If not, we wait. =3.	3
f	Gale	No, we stay home. =1.	1
g	Storm	No, we stay home. =1.	1
h	Are there any of these in combination that affect how likely it is that you go out and fish?	Wind has the greatest impact here. Wind direction matters too (this August mostly W & NW winds, cooling the water – no point fishing perch then, they just stop moving).	NA

Q 3 - catchability

Do you experience that the catchability of the fish changes due to such extreme weather events?

[1–5; from 1 – much worse, 3 – no difference, to 5 – much better]

Table S.102: Interviewee: I 3 Q 3

Table S.147: Interviewee: I 3 Q 47

Answer	Score
Same answer if you ask other fishers with a similar business	1

Interviewee: I 4

id4 is a resident of the archipelago in the northern proper baltic (hasselÅ¶, tjust archipelago). archipelago fisherman cannot sell their catchers. in the past, there was a very diversified fishing community with various types of nets for coastal and freshwater species. nowadays they continue to fish with nets for perch, herring, whitefish. he mentions also the importances of being able to catch fish with rods, but in the second interview he only refers to fishing with nets. fishing mostly happens during summer (april to august), winter fishing is less common but can happen. he mentions that if the water is free from ice they can cast nets also in winter. how they adapt: id4 is not economically dependent on fishing and in general tend to do it only when there are good conditions. he can adapt to hw by performing shorter (not overnight) sets. can also adapt to hw, ab and storms by changing fishing location. to avoid hw and ab they can go further out, the opposite for storms. in any case they can move on very short distances. their spatial mobility is mainly affected by its assigned fishing lot.

Q 2 - go_fishing

If the following type of extreme event occurs, how likely is it that you go out and fish?

[1–5; from 1 – very unlikely, to 5 – very likely]

Table S.148: Interviewee: I 4 Q 2

	Event	Answer	Score
a	Heatwave in the winter season	Quite likely, if the water is open we'll go out, 4	4
b	Heatwave in the summer season	2. Depends on how it affects winds and algal blooms; this year we had huge problems with algal blooms (1 month).	2
c	Severe icing (in the winter season)	No problem for us, too far south.	-999
d	Algal bloom (in the summer season)	1	1
e	Extreme cloudburst (in the summer season)	We can get to the boathouse, but from there out onto the lake it's more difficult; 1, if we don't have gear in the water. But we check the weather forecast very carefully before putting in the gear.	1
f	Gale	1	1
g	Storm	1	1
h	Are there any of these in combination that affect how likely it is that you go out and fish?	Strong winds and high water levels.	NA

Q 3 - catchability

Do you experience that the catchability of the fish changes due to such extreme weather events?

[1–5; from 1 – much worse, 3 – no difference, to 5 – much better]

Table S.149: Interviewee: I 4 Q 3

	Event	Answer	Score
a	Heatwave in the winter season	NA	2
b	Heatwave in the summer season	Yes, in the past when perch existed, they liked warmth, but now there are no perch, so the effect is not so big on the species we fish for	3
c	Severe icing (in the winter season)	NA	-999

d	Algal bloom (in the summer season)	It's devastating, depressing to live around this algal soup, grandchildren can't swim, it's an imbalance in the Baltic Sea ecosystem, a sad new phenomenon. We try to deal with it when it drifts ashore. It becomes a white coating on the bottom when it sinks. We're worried about algal toxins (cows can break them down somewhat, but single-stomached animals can't; affects the liver). 1.	1
e	Extreme cloudburst (in the summer season)	No, 3	3
f	Gale	A little worried about strong winds since we don't have big boats.	2
g	Storm	Same with storms.	2

Answer	Score - low (given)	Score - up (given)	Unit
I think we've gone through most of it. Water levels: your report mentions it, and many are concerned about low water levels, which indeed happened; but high water is just as problematic – wading out to the boathouse in waders.	NA	NA	not_reported

Q 44 - unc_36_42

How much do you think the answers to these questions (questions 36–43) vary between fishers in the group you represent?

Table S.191: Interviewee: I 4 Q 44

Answer	Score
There are some who have fishing rights but don't fish at all, and then some who fish like I do, just now and then. Then there are those who have leased out their fishing lot, and in those cases there is a subsistence fisher who fishes quite intensively	5

Q 45 - addition

Anything you want to add?

[free text description]

Table S.192: Interviewee: I 4 Q 45

Answer	Score
--------	-------

Regarding innovation: we're interested in all cooperation with experts who can help us restore ecological balance in the Baltic Sea.	-
There is interest moving forward. What I pick up is that we must do something about the algal blooms. Maybe find a way to collect them with boats; there is centrifuge competence in Sweden	999

Q 46 - substitution_capacity

If I lose one planned fishing day, I can usually make up for it later without it affecting what I achieve overall
[1-5; from 1 – strongly disagree, to 5 – strongly agree]

Table S.193: Interviewee: I 4 Q 46

Answer	Score
A lost fishing day does not constitute an impact because the fishing is not of economic importance.	5

Q 47 - unc_46

How much do you think the answers to these questions (question 46) vary between fishers in the group you represent?

Table S.194: Interviewee: I 4 Q 47

Answer	Score
Other subsistence fishermen will surely answer the same.	1

Interviewee: I 5

id5 represents the organization sportfiskarna, which is active in all sweden. he is based in stockholm. the members of sportfiskarna are anglers that mostly fish for pike, perch and zander. additionally, fishing for sea trout and trolling for salmon is common. they fish in lakes, streams and coastal areas. they can use boats in coastal areas and lakes, or just fish from the shore. in winter they also do ice fishing on lakes and generally they do not use boats until the ice is completely gone. the members practice both catch-and-release and keeping the catch. recreational fisherman can move around different fishing spots. how they adapt: sportfisherman are diverse but have in common to fish exclusively for fun. they tend to fish only when it is a pleasant experience. they can cope to some extent with extreme events by adapting their location if they want to fish on the coast (going deeper or finding sheltered places) or move to lakes. their spatial mobility has virtually no limits.

Q 2 - go_fishing

If the following type of extreme event occurs, how likely is it that you go out and fish?
[1-5; from 1 – very unlikely, to 5 – very likely]

Table S.195: Interviewee: I 5 Q 2

Event	Answer	Score
-------	--------	-------

a	Heatwave in the winter season	If it's otherwise a good winter, then it's just nice weather. But if it's a mild winter, then you can't go out. Is ice fishing the dominant form? Few go out in boats? On the big lakes. and at Simrishamn there is some trolling from boats. If we think about ice fishing? Absolutely, =1 if the ice isn't there or is dangerous to walk on.	1
b	Heatwave in the summer season	Yes, but in another way. When it's hot, fishing in running waters (salmon, trout, grayling) is closed. Perch and zander fishing only gets better in warm weather. Few target pike in a heatwave. But if you booked a salmon-fishing week, it simply gets canceled. Zander & perch = 5; salmon & trout = 1; pike = 2 (or 1, discussed with another angler present). But "vacation fishers" will probably go out regardless. Pike fishing is usually in spring & autumn; high temps affect survival.	NA
c	Severe icing (in the winter season)	Big impact.	1
d	Algal bloom (in the summer season)	Less attractive, but still possible to fish; =2.	2
e	Extreme cloudburst (in the summer season)	People hold back; it's a comfort factor. Most stay indoors	2
f	Gale	Yes, people hold back; most stay home, except the really keen ones who may go out in sheltered spots	2
g	Storm	No, impossible to fish.	1
h	Are there any of these in combination that affect how likely it is that you go out and fish?	Combination of gale/storm and heavy rain – Even more unpleasant, a negative synergy effect	NA

e	Extreme cloudburst (in the summer season)	no	3
f	Gale	no	3

Q 6 - cope_condition

If the condition/quality of the fish in the catch is negatively affected, how likely is it that you can do something about it? Explain what!

[1–5; from 1 – very unlikely, to 5 – very likely]

Table S.201: Interviewee: I 5 Q 6

	Event	Answer	Score
a	Heatwave in the winter season	NA	-999
b	Heatwave in the summer season	No, nothing can be done. If fish are in poor condition, there's nothing you can do. Doesn't really apply to sport fishing since fish aren't trapped in gear	1
c	Severe icing (in the winter season)	NA	-999
d	Algal bloom (in the summer season)	NA	-999
e	Extreme cloudburst (in the summer season)	NA	-999
f	Gale	NA	-999
g	Storm	NA	-999

Q 7 - lag_effect

Do this extreme weather events have long-term effects on how you fish or catch composition

Greatest effect is probably on Arctic char (though not a major sportfishing species). Other species may move in: grayling, trout, whitefish, perch & pike. Biggest sportfishing impact from extreme weather is likely on char. On the coast, fish can always go deeper. Does it affect how you fish? Yes – e.g., trout anglers (spring & autumn from shore) may need to fish deeper or at different times. On Gotland, sea trout fishing is big – if warming lasts longer, the season gets shorter until it cools again.

It might vary a lot among fishers. If you have booked a guide or an arrangement, a lost day might be difficult to recover. If you just go out fishing in your "home waters" it might be less of a loss. So substantial variation across fishers.

Interviewee: I 6

id6 fish pelagic fish both in the baltic sea and the north sea. in the baltic sea, the fishing targets herring/sprat and sharp-sprat, and the catch is sent to fishmeal. in the baltic sea, lars-uno fishes from the southern baltic up to the bothnian sea (at the level of sundsvall). they can occasionally fish in outermost regions (shetlands). the main fishing season is from august to april (but the season can extend longer into spring and summer), and the current law does not establish any limitation regarding time at sea (e.g.: seasonal ban, weekend ban). their activity is limited by the quota. in winter their activity in the baltic might be affected by ice coverage. how they adapt: pelagic trawlers have a great spatial mobility because of their large size vessels. their primary method to adapt to weather is to move around: they may switch from an area to another when they know the climatic conditions (i.e.: water temperature) are good. in the case of local weather is not good they stay in port. they have efficient cooling systems to deal with hot weather.

Q 2 - go_fishing

If the following type of extreme event occurs, how likely is it that you go out and fish?

g	Storm	You can go ashore and unload what you have. 3	3

Q 7 - lag_effect

Do this extreme weather events have long-term effects on how you fish or catch composition

4, we saw that mackerel migrate, but the funny thing is that they are starting to come back again, as they did 20 years ago. I don't know if this has anything to do with the heat, or if it's a cycle; mackerel have been north of Shetland, but now it seems that they are back in Norway again; perhaps they will return to how it was 20-25 years ago; In the Baltic Sea, I think cod has been affected because it has gotten warmer. Thirty-five to forty years ago, the entire Baltic Sea was frozen, but sprat and herring have increased in the last five years. Smelt has also recovered because it has gotten warmer. Yes, it has affected us.

Answer	Score
In terms of extreme weather with storms, I think we've covered everything; this large variation in temperature in the Baltic Sea is something you're looking at, I think, with temperature data from SMHI.	- 999

Q 46 - substitution_capacity

If I lose one planned fishing day, I can usually make up for it later without it affecting what I achieve overall [1–5; from 1 – strongly disagree, to 5 – strongly agree]

Table S.290: Interviewee: I 6 Q 46

Answer	Score
Because of the ITQ system, we can wait until the weather conditions improve. Before this system was implemented, people went out and fished despite the risks involved.	5

Q 47 - unc_46

How much do you think the answers to these questions (question 46) vary between fishers in the group you represent?

Table S.291: Interviewee: I 6 Q 47

Answer	Score
Same answer if you ask other pelagic fishers	1

Interviewee: I 7

id7 is a professional coastal fisherman in the southwestern bothnian sea (Älvsgrund area?). they fish with gillnets and traps. the main fishing season is summer. they can do some ice fishing. the main target is herring, whitefish, salmon, perch. they have more salmon traps than the average coastal fisherman. fishing for perch (nets) is done from a small boat close to home, while fishing for herring happens with a larger boat more far away. a trip for herring can cost up to 100 litres of diesel (approximately 10 l*hour at 10 knots means that they can go to cast at least 50-60 km from home). how they adapt: they primarily adapt when fishing with nets to hw by changing fishing target. when it's hot they aim for perch and not for herring. in addition, they can perform shorter sets and use cooling boxes. can also adapt to hw and storms by changing fishing location. they are not affected by ab. to avoid hw they can go further out in deeper waters, the opposite for storms. in any case they can move on short distances. their spatial mobility is mainly affected by the boat and infrastructure (they want to go back home) on second instance by management that makes possible to fish in proximity. there is not the same flexibility for salmon traps, which are fixed.

Q 2 - go_fishing

If the following type of extreme event occurs, how likely is it that you go out and fish?

[1–5; from 1 – very unlikely, to 5 – very likely]

Table S.292: Interviewee: I 7 Q 2

	Event	Answer	Score
a	Heatwave in the winter season	I probably go fishing anyway, it's the wind that matters, I probably try anyway (=5? or =4?)	4.5
b	Heatwave in the summer season	I don't go because the fish won't keep as well, I don't fish for herring at all, in that case I fish for perch, 2	2
c	Severe icing (in the winter season)	I am not on the lake at that time of year when there is a risk of icing (because the ice forms so early	-999
d	Algal bloom (in the summer season)	I have not experienced it, but it probably has an impact, so then I don't fish	-998
e	Extreme cloudburst (in the summer season)	then I fish anyway	4
f	Gale	depends on the wind direction, if it's N then it's from the outside so then it's difficult, if it's S or SW, in gale force winds I don't fish anyway because there's a strong current in the lake so you get crap in your nets, but I do go out in gale force winds sometimes , depends on the wind direction	3
g	Storm	1	1
h	Are there any of these in combination that affect how likely it is that you go out and fish?	storms and weather like that	NA

Treatment of fisheries statistics available in European and Swedish repositories

Data sources by fishing style

Commercial fishers

Data for fishery dependent information for professional commercial fishers are available through the European Data Collection Framework, of which most recent update at the time of writing includes data until 2024. Our case study area spans over four ICES statistical divisions (northern part of 27, 29, 30, 31; Fig. B1). The majority of the commercial fishers included in our dialogues operate in the area 30 (Bothnian Sea), which is chosen as reference area for statistical information. The dataset relevant for this study includes:

- *Fishery dependent information (FDI) for EU Fleets* [jrc]: provides fishing effort (dataset D1; fishing days) and catch (dataset D2; weight and value) data by country, area, fleet segment and target species
- *Annual Economic report on EU fishing fleet* [jrc2025]: provides economic overview (dataset D3; number of vessels, income, expenses) of european fishing fleets by country and fleet segment

The FDI data resolution allow us to obtain information for the study area (Bothnian Sea - ICES area 27.3.D.30), while the AER is only available at country (Sweden) level. Different aggregation of the data requires to implement some simplifications or assumptions, hereby explained. Terminology adopted is consistent with definitions in use in the Data collection framework of the European Union [gear2026].

Small scale fishers Small scale fishers catch and effort data correspond to vessels of size $< 12\text{m}$, deploying passive gears and operating in the sub-region 27.3.D.30. This region includes the majority of small scale coastal fishers deploying gillnets in Sweden, especially for those targeting Herring (more than 50% of total fishers with GNS-SPF metier are registered in the study area). Economic data for the fleet segments, although refers to values at country level, are considered to be representative of the study area.

Pelagic trawlers Pelagic correspond to vessels of size $> 24\text{m}$ operating pelagic nets (gear code: Trawl Midwater - TM) in the sub-region 27.3.D.30. Pelagic trawlers move between Swedish areas, and the same fleet can report catches in several divisions. Economic data at country level are therefore an appropriate aggregation. However, given the very small number of active vessels, Sweden does not provide economic data at fleet segment level for confidentiality reasons [jrc2025]. Economic data are provided for the aggregated Large Scale fleet, which includes vessels $> 24\text{m}$ operating demersal trawlers, pelagic trawlers and purse seiners. On average, over the period 2020-2025 40 % of landed value.

Recreational fishers

Dataset for recreational fishers is available through Sweden statistic reports [swam2024], which most recent update at the time of writing includes data until 2024. The dataset relevant for this study are the following tables (table number is reported as it appears in SwAM and SCB, 2024):

- Table 5: target species in the sea in 2024
- Table 6: primary and secondary gear used in recreational fishing in 2024
- Table 8: Catches in recreational fishing in the sea in 2024
- Table 9: Expenditures in recreational fishing in 2024, million SEK

Dataset ID	Dataset_name	Description
D1	fdi_effort_SWE.csv	Fishing effort for commercial fisheries from FDI data call [@jrc]
D2	fdi_catch_SWE.csv	Catches for commercial fisheries from FDI data call [@jrc]
D3	fdi_SWE.csv	Economic overview (number of vessels, income, expenses) of european fishing fleets [@jrc2025]
D4	rec_gears_SWE.csv	Thousand of practitioners reported for recreational fishing technique in Sweden
D5	rec_catch_SWE.csv	Thousand of practitioners reported for target species in Sweden
D6	rec_economics_SWE.csv	Economic and fishing effort data

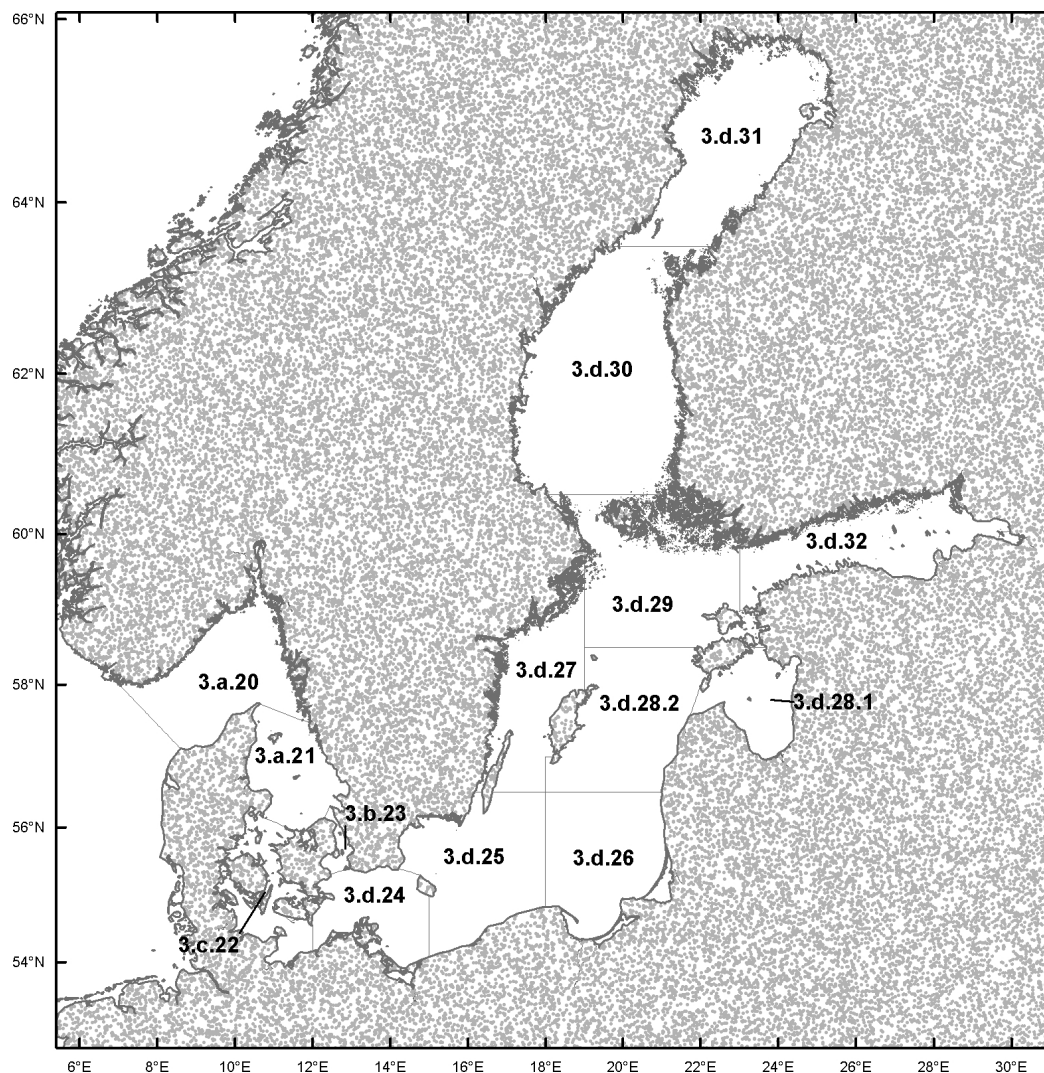

Figure S.1: Map of the Baltic Sea (numbers indicate the statistical divisions for fisheries data collection). The study area spans across Swedish fisheries in areas 3.d.31, 3.d.30, 3.d.29 and the northern part of 3.d.27.

Fishing gears

Exploration of fishery statistics data

Small-scale coastal fishing We analysed dataset D1, subset to ICES area 27.3.D.30, Swedish country code, vessels categories VL0812 and VL0008 to identify the mostly used métiers by the Small-scale coastal fishing (ssf). A **métier** is defined as group of fishing activities targeting a similar species or assemblage of species, using similar gear [dcf2021]. Figure B.2 shows average total fishing days by métier over the available data (years 2008-2024). We select for consideration in our study the métiers (1) gillnets-freshwater species (GNS-FWS), (2) gillnets-small pelagic species (GNS-SPF), (3) pound nets- anadromous species (FPN-ANA). The sum of average fishing days for the three selected métiers accounts for 85% of total fishing days for ssf in our study area.

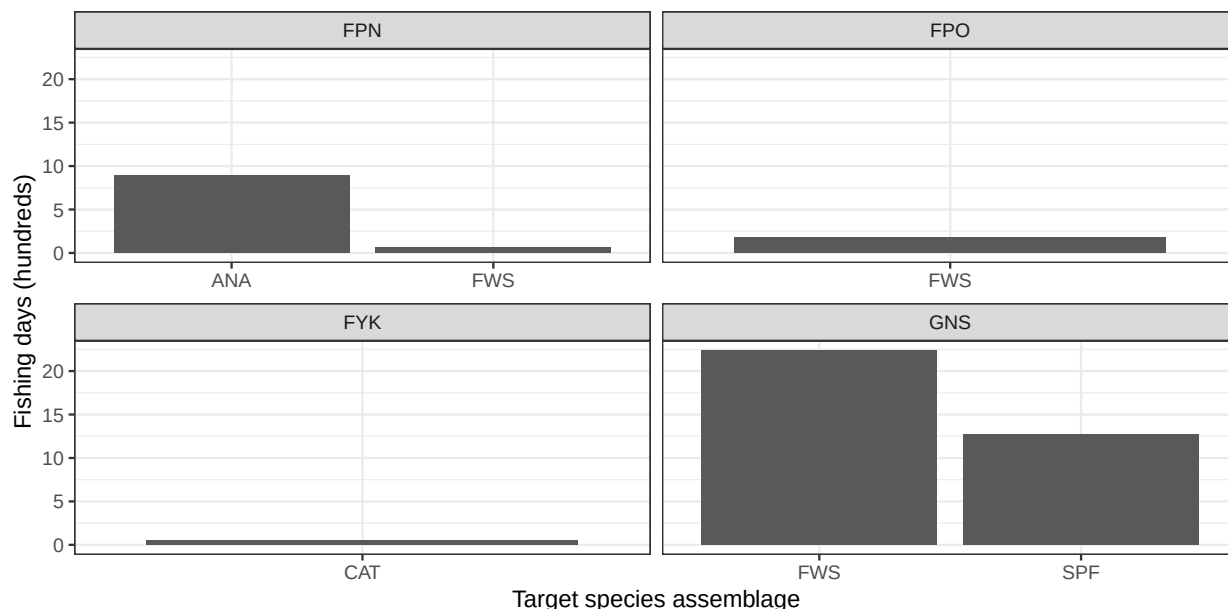

Figure S.2: Fishing days by metier, swedish small scale coastal fleet in Bothnian Sea. Panels represents gear type.

Pelagic trawling and large scale fleet We analysed dataset D1, filtered to Swedish fleet, vessels categories VL2440 and VL40XX, to assess the fishing effort distribution by fishing technique in the Swedish large scale fleet. This information supports the interpretation of economic data, for which data are aggregated across fishing techniques. Figure B.3 shows that the fishing technique *Demersal Trawl Shelf* (DTS) and *Trawl Midwater* (TM) includes similar amount of fishing days, and together represents the vast majority of Swedish fishing effort. In the DTS category, pelagic trawling gears (OTM, OTT, PTM) dominates the fishing activity.

Recreational fishing Dataset D4 shows the number of practitioners by recreational fishing method. Fishing methods based on hook and lines are dominating the distribution reported in Fig. B.4. Cages and nets are the two main techniques that do not base on hook and line. Cages are predominantly used in crustaceans fishery on the west coast of Sweden. The use of nets is popular in the Baltic Sea. For the purpose of this study we consider that only hook and line methods apply for the recreational fishing style, with no distinction among methods. Nets applies to the household fishing style.

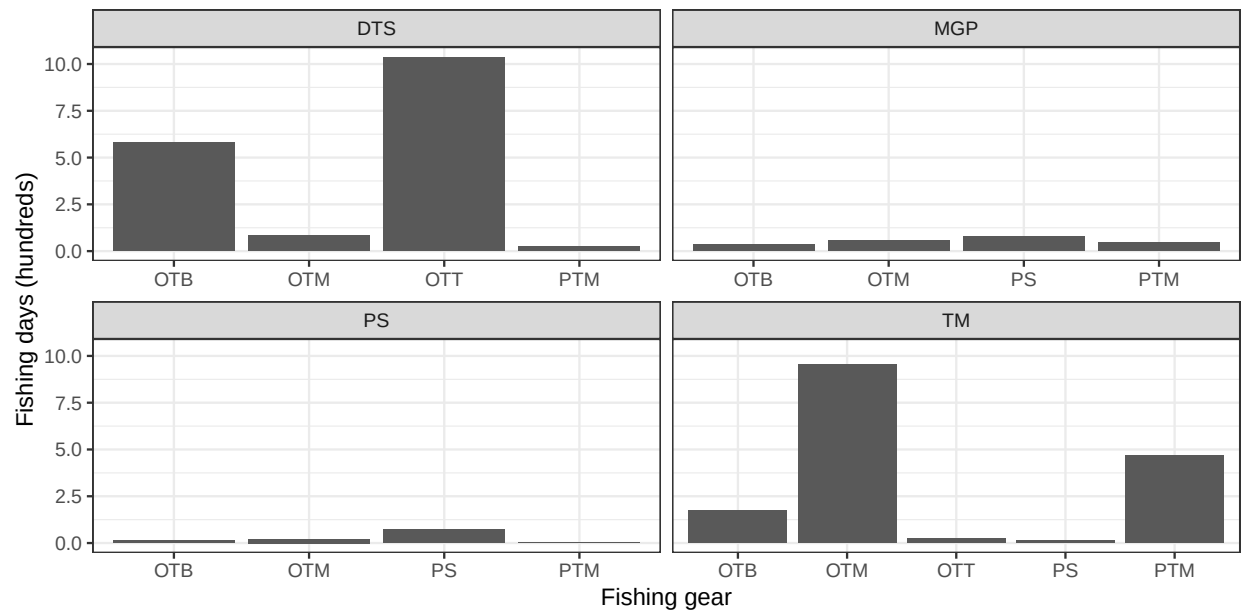

Figure S.3: Fishing days by gear and fishing technique, swedish large scale fleet. Panels represents fishing technique.

Fishing target

Exploration of fishery statistics

Small-scale coastal fishing We analysed dataset D2 to identify the catch composition associated to ssf métiers selected in the previous section. The dataset, filtered to Swedish fleet in ICES area 27.3.D.30, vessels categories VL0812 and VL0008, was subset to match the ssf métiers (1) gillnets-freshwater species (GNS-FWS), (2) gillnets-small pelagic species (GNS-SPF), (3) pound nets- anadromous species (FPN-ANA). Species scientific name were assigned according to ASFIS List of Species for Fishery Statistics Purposes [fao2026].

Catch data were aggregated by metier and averaged over years. We calculated the cumulative contribution of each species to a metier and we excluded species falling beyond the 95th percentile. Figure B.5 shows average tons by species and metier over the available data (years 2008-2024). The species mostly represented are Atlantic herring (target of gillnets for small pelagic fish), Atlantic salmon (main target of pound nets for anadromous species), European perch (main target of gillnets for freshwater species). Whitefish is also considered a relevant species as it significantly contribute to catches for FPN-ANA and GNS-FWS.

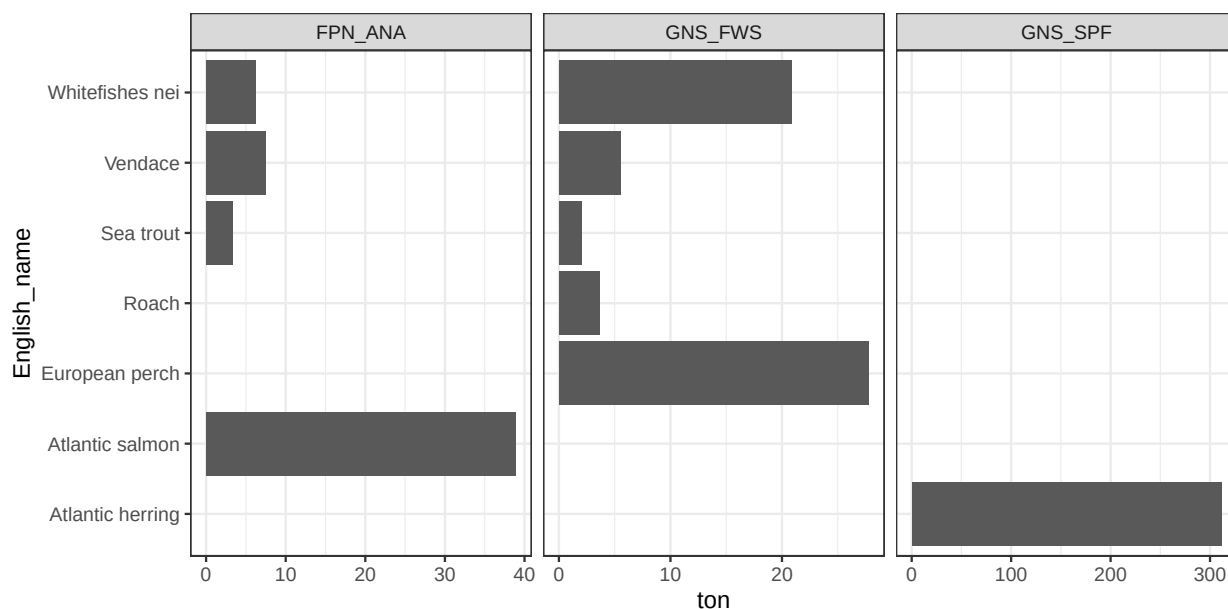

Figure S.5: Catches by metier, swedish small scale coastal fleet in Bothnian Sea (selection of metiers)

Pelagic trawling and large scale fleet We analysed dataset D2 to evaluate the catch value associated with fishing gears deployed by Swedish large scale fleet, and then the catch composition of pelagic trawlers. The economic value of catches, filtered to Swedish fleet in ICES area 27.3.D.30, and vessel categories ‘VL2440’, ‘VL40XX’ was aggregated by metier and averaged over years. Figure B.6 shows that pelagic fleet (TM) dominates the distribution (58% of total), and the fishing gears Otter Trawl Midwater (OTM) contributes nearly to 37% of the entire landed value.

To explore fishing target of the pelagic trawl fleet in the study area, dataset D2 was subset to match the gear type “OTM”, Swedish fleet in ICES area 27.3.D.30, and vessel categories ‘VL2440’, ‘VL40XX’. Species scientific name were assigned according to ASFIS List of Species for Fishery Statistics Purposes [fao2026]. We calculated the cumulative contribution of each species to a metier and we excluded species falling beyond the 99th percentile. Figure B.7 shows that Atlantic herring contributes for more than 97% of average catches. For pelagic trawlers we therefore consider Herring as the only relevant species.

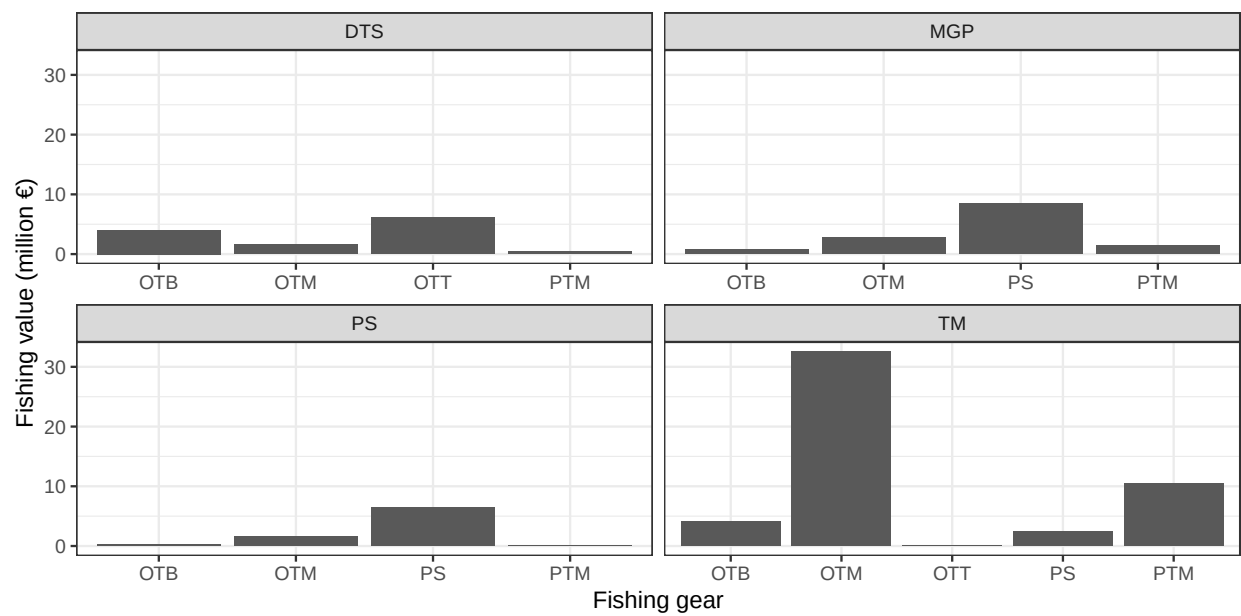

Figure S.6: Catches by gear and fishing method, swedish large scale fleet

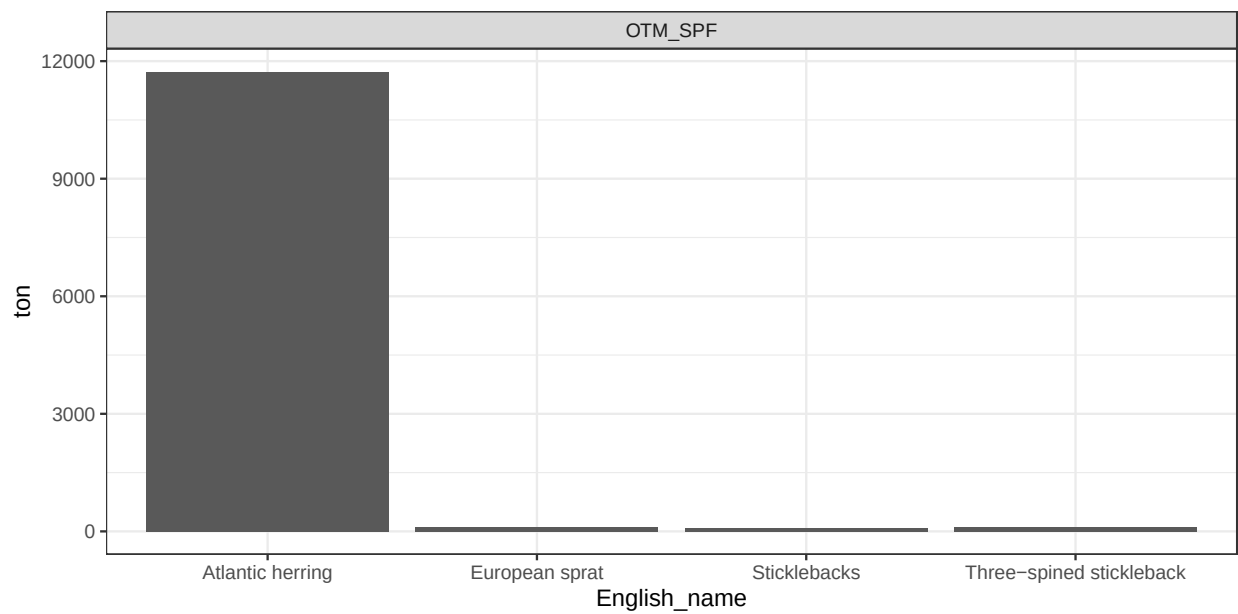

Figure S.7: Catches for pelagic trawlers, swedish fleet in Bothnian Sea

Recreational fishing For recreational fishers we are interested in the distribution of number of practitioners by target species, in the Sea. Dataset D5 was subset to exclude species that are not available in the Baltic Sea. Fig. B.8 shows that Perch and pike dominates the distribution. We excluded some relevant species (Cod, Zander) for simplifying the model. Whitefish was included, although not contributing substantially to recreational fishing target, because it is a shared resource with small scale fishers.

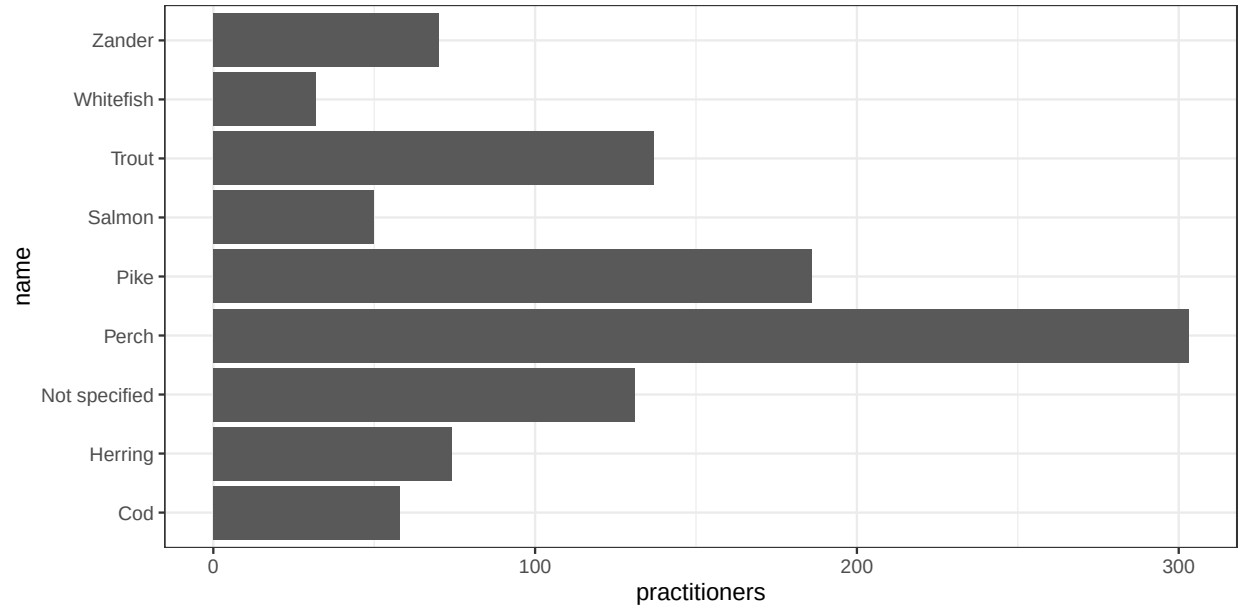

Figure S.8: Catches for recreational fishers

Assignations

Table S.345: Baseline fishing gear assignation

target	otm	gns_fws	gns_spf	fpn_ana	lhp	icefishing	inland
herring	1	0.00	0.99	0.00	0.07	0.00	0
perch	0	0.44	0.00	0.00	0.29	0.33	0
pike	0	0.00	0.00	0.00	0.18	0.33	0
salmon	0	0.00	0.00	0.66	0.05	0.00	0

whitefish	0	0.42	0.00	0.23	0.03	0.33	0
not_specified	0	0.10	0.01	0.05	0.25	0.00	1

Economic data

Methods

The cost node reflects the economic impact of one single extreme weather event compared to annual average expenses. Cost categories to be used in the conditional probability table are: *negligible* (cost < 0.05%); *low* (0.05% < cost < 2.5%); *medium* (2.5% < cost < 5%); *high* (> 5%).

The conditional probability tables are estimated through the function `cost.cpt`, here below reported. The input needed are:

- expenses (mu and sd): annual total expenses, including maintenance, fuel, personnel. This value is anchored in literature, when available;
- fuel.cost (mu and sd): average cost for single fishing trip. This value is anchored in literature, when available;
- damage.small (lo and hi): self declared cost for repairing a minor damage;
- damage.large (lo and hi): self declared cost for repairing a large damage;
- damage.unc: self declared uncertainty on the cost for repairing damages;
- fuel.avg (lo and hi): self declared fuel consumption for single average fishing trip;
- fuel.large (lo and hi): self declared fuel consumption for single longer-than-average fishing trip;
- miss.catch (mu and sd): average gross economic value of catches from one fishing day
- economic.unc: self declared uncertainty associated with answer regarding expenses;
- fishing style: label describing the fishing style.

```

Small-scale coastal fishing

Economic information for small scale coastal fishers, available in dataset D3 (Table C.1), filtered for vessel length categories VL0010 and VL0812, fishing technologies FPO and DFN and Swedish country code. Cost of fuel per trip is calculated by dividing total fuel expenses by number of fishing trips. Annual spending is estimated by dividing total annual expenses by number of fishing vessels. Gross value of catches in a single fishing trip is obtained by dividing total annual value of catches by number of fishing trips. Other values are provided in the interviews.

Table S.346: Variables from interviews

id_I	short_description	range.lwr	range.upr	unit_range
2	minor_damage_cost	10000	50000	sek_unit
3	minor_damage_cost	1	50000	sek_year
7	minor_damage_cost	1000	50000	sek_unit
2	major_damage_cost	100000	500000	sek_unit

3	extra_fuel	3000	5000	sek_day
7	extra_fuel	50	100	B liter_trip

Table S.347: Variables from literature

variable	value_mean	value_sd	unit	source
Annual expenses	1702	1567	thousand SEK	STECF_AER
Fuel cost	6670	8668	SEK	STECF_AER

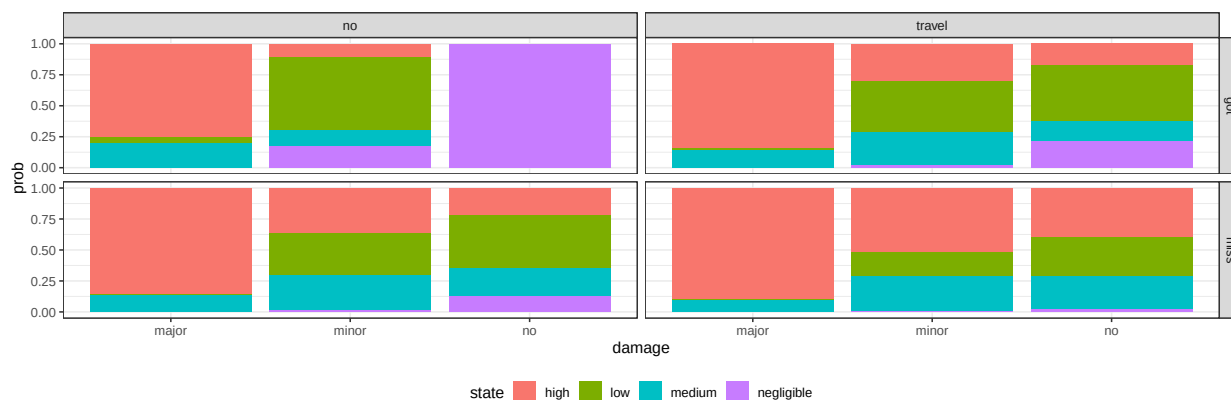

Figure S.9: CPT estimated for coastal fisherman

Pelagic trawling

Pelagic economic information is derived from dataset D3, filtered for vessel length categories VL2440 and VL40XX, and Sweden country code. Cost of fuel per trip is calculated by dividing total fuel expenses by number of fishing trips. Annual spending is estimated by dividing total annual expenses by number of fishing vessels. The cost of longer travel was not available, and it is based on the assumption that an average travel costs between 80% and 120% of the average fuel cost, while a longer travel is between 100% and 300% of average fuel cost. Other values are provided in the interviews.

Fuel cost	259142	117662	SEK	STECF_AER

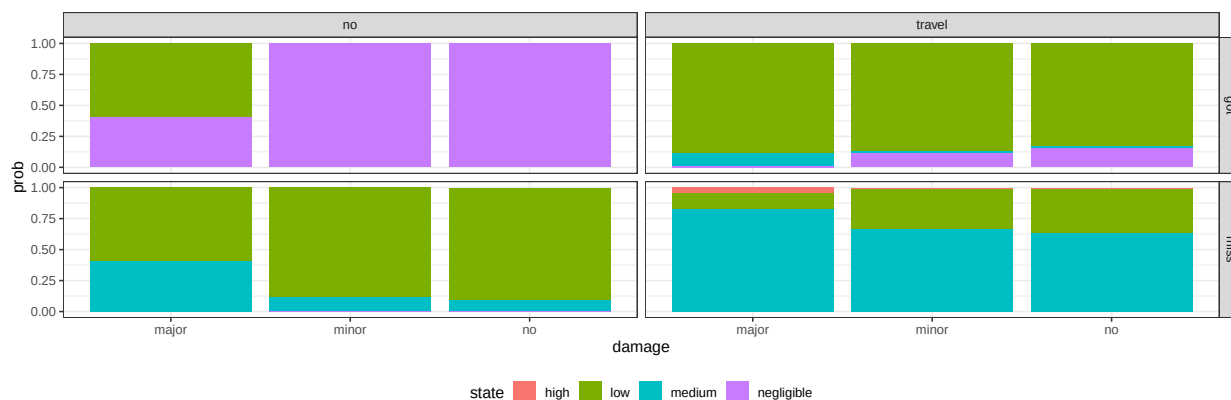

Figure S.10: CPT estimated for pelagic trawlers

Recreational fishing

Economic information is derived from dataset D6, representing the totality of recreational fisherman in Sweden with no distinction between region or inland vs coastal fishing. Cost of fuel per trip is separately calculated for travel and for boat fuel. These two costs are then averaged. All the uncertainties (on costs and on number of practitioners) are accounted for by propagating errors. Annual spending is estimated by dividing total annual expenses by number of practitioners. Other values are provided in the interviews.

Conditional probability tables

Network structure

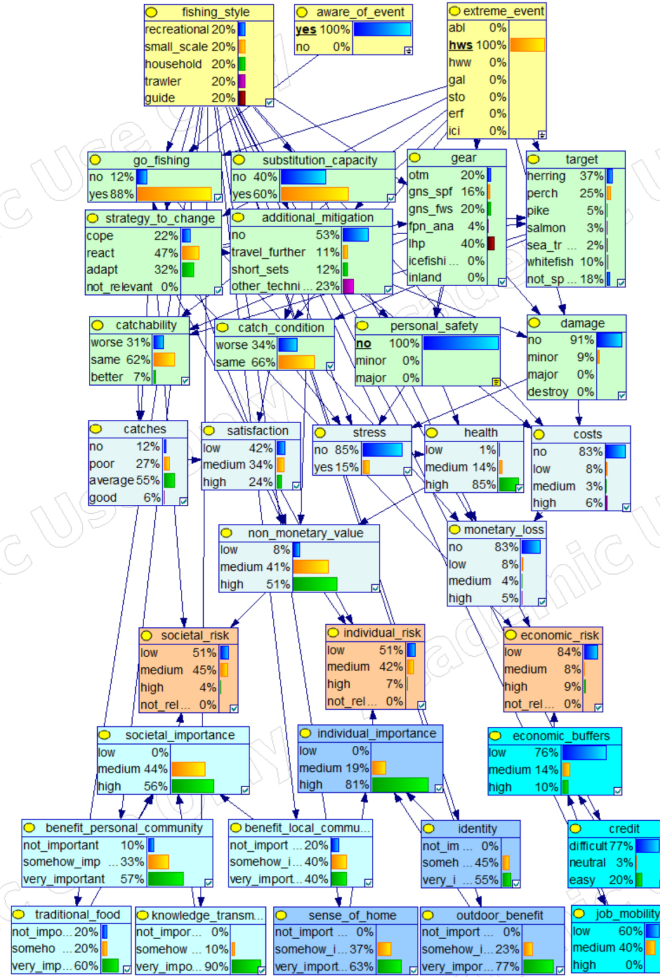

Figure S.14: Bayesian Network representing risks to Swedish fisheries posed by Marine Extreme Weather events (abl algal bloom, hws summer heatwave, hww winter heatwave, gal gale, sto storm, erf extreme rainfall, ici icing) effects on fishing operations, as identified at the conclusion of the third cycle of stakeholder (fishers) dialogues. The probability distributions shown in the boxes represents the example of how summer heatwave affects fishing operations across all fishing styles. Conditional probability distribution details and terminology are reported in Supp. Info. C. Colors are associated to node types and group Yellow: decision nodes; lime green: chance nodes – operational group; grey: chance nodes - user group; navy blue: chance nodes - individual group; light blue: chance nodes - societal group; cyan: chance nodes - economic group; orange: risk nodes

Algebraic methods for Ranked nodes

Ranked nodes have order-preserving meaning states (e.g.: low/medium/high) that can be mapped to a continuous numerical scale bounded to $[0,1]$, assuming equal intervals [fenton2019]. For instance, in a node having three states (low, medium, high), the “low” state takes the interval $[0-0.33)$. The probability distribution of a ranked node in the numerical scale is described as $TNormal(\mu, \sigma^2, 0, 1)$. The use of a numerical scale allows us to use linear algebra to perform operations among variables, a technique that is particularly useful to build a CPT from a reduced number of questions [fenton2007]. When a child has multiple parents with multiple states (binary or more), the distribution of a child node can be calculated by implementing algorithms based on the state, direction (positive or negative) and weight of their parents. The algorithms most commonly applied to ranked nodes gives equal (Eq. B1) or unequal contribution to states. Weighted max (Eq. B2) assigns more contribution to large states, while Weighted min (Eq. B3) assigns more contribution to small states.

$$\mu = \frac{\sum_{i=1}^n w_i X_i}{\sum_{i=1}^n w_i}$$

[Eq.C1]

$$\mu = \min\left[\frac{w_i X_i + \sum_{i \neq j}^n X_j}{w_i + (n - 1)}\right]$$

[Eq.C2]

$$\mu = \max\left[\frac{w_i X_i + \sum_{i \neq j}^n X_j}{w_i + (n - 1)}\right]$$

[Eq.C3]

Decision nodes

Extreme weather events (node: `extreme_event`)

The node *extreme_event* is used to wrap all the extreme weather events we are considering.

Levels (and acronyms)

- **Storms** (sto). Strong wind events, with intensity above 24.5 m/s. Season: summer.
- **Gales** (gal), or moderately strong wind events, with intensity between 15 m/s and 24.5 m/s;
- **Extreme precipitation** (erf) – rainstorm (summer), or deviation from average precipitation regime;
- **Algal bloom** (abl): intense algal bloom;
- **Summer heatwaves** (hws): prolonged discrete anomalously warm water event occurring in summer (Hobday et al., 2016);
- **Winter heatwaves** (hww): prolonged discrete anomalously warm water event occurring in winter (Hobday et al., 2016);
- **Icing** (ici): strong wind events associated to ice, which then forms icing pile up on gears and boats.

Fishing style (and acronyms)

The node *fishing_style* is used to wrap all the fishing styles and seasons.

Levels (and acronyms)

- **Recreational fisher (recreational - rcf)**: fishers without a commercial fishing license, deploying hand-held gears for recreational purposes;
- **Fishing guides (guides - fgu)**: commercial actors who provide recreational fishers with fishing experience by sharing expert and local knowledge, giving access to angling concession and offering boat chartering ;
- **Small-scale coastal fishing (small_scale - ssf)**, fishers operating small boats (<12 m) deploying species-specific passive gears.
- **Pelagic trawling (trawlers - trw)**, fishers operating medium to large size vessels (24-60 m) deploying pelagic trawl nets;
- **Household fishing (household - hou)**, fishing by residents of the Swedish archipelago, using coastal-type passive gears, without commercial licences and without legal access to markets.

Aware of the event

The node *aware_of_event* controls the fisherman awareness of the event occurrence. In the case when fisher is not aware, they always goes out fishing. The fisher can still adopt react or adapt str

Levels (and acronyms)

- **yes**: the fisher is aware of the extreme event. Decisions whether to go out fishing or not are taken according to interviews
- **no**: the fisher is not aware of the extreme event. The probability of going out fishing are 100%

Chance nodes - Operational

Strategy to_change

Parents: fishing_style, extreme_event.

Levels: cope, react, adapt, not_relevant.

Description: Fishers strategy is coded as adapt, react or cope (Green et al., 2021). Adapt is proactive planning, it implies large changes in fishing strategy (i.e.: changing fishing target and/or gear). React is unplanned response, or small modification to fishing practice (fishing in a diferent location or in different time of the day). Cope is passively accepting consequences, it implies no modifications at all to the fishing strategy.

Method: Case C1. We interpreted narrative (especially questions Q 2, 4, 13 and 15) to associate one or more among Adapt, React or Cope to each combination of fisher and MEW. The question chosen to fill the CPT depends on the narrative.

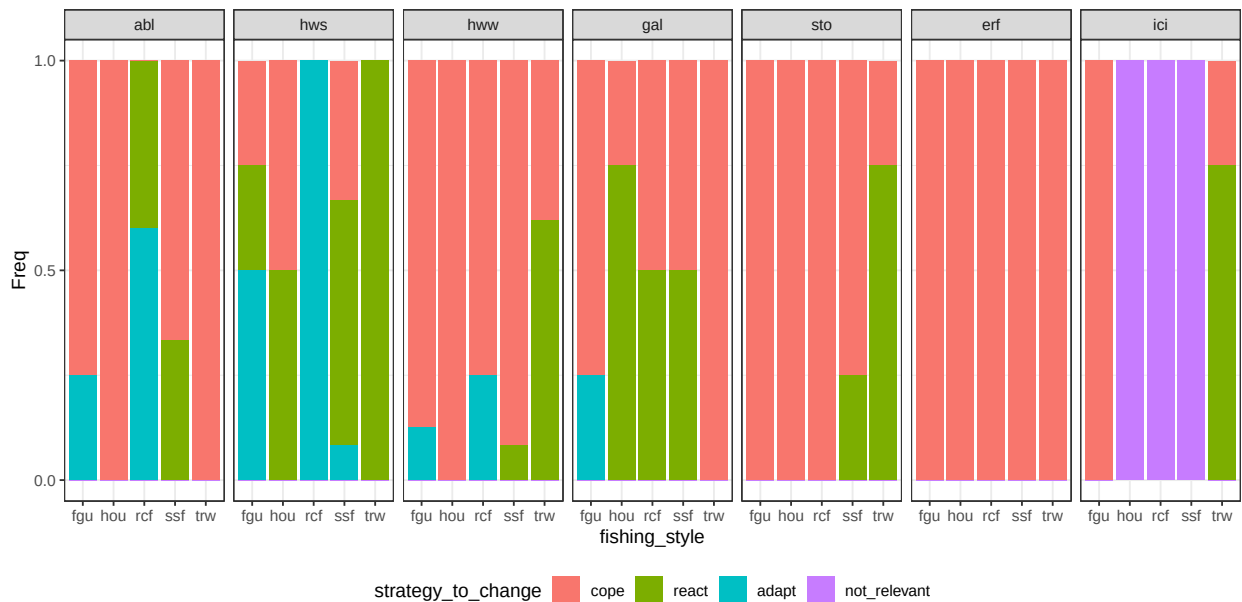

Figure S.15: conditional distribution for strategy_to_change. Columns represents levels of the node extreme_event.

Additional mitigation

Parents: strategy_to_change, fishing_style, extreme_event.

Levels: no, travel_further, short_sets, other_technical.

Description: Measures implemented in the case when the strategy is React. The different solutions work differently and have different cost: travel further implies fishers change fishing location to seek a sheltered place or to find deeper waters; short sets mean that the fisher perform shorter sessions than average (i.e.: reduced soak time for gillnets); other technical includes strategies that are mentioned sporadically (i.e.: use of ice machines).

Method: Case C4. We interpreted narrative to associate one or more solution to each combination of fisher and MEW. In case only one strategy is mentioned, this is assigned probability = 1. When two or more strategies are mentioned, they are given equal probability unless explicitly indicated in the interviews.

Figure S.16: conditional distribution for additional_mitigation. Columns represents levels of the node fishing_style; rows are levels of the node extreme_event.

Gear

Parents: fishing_style, extreme_event, strategy_to_change.

Levels: otm, gns_spf, gns_fws, fpn_ana, lhp, icefishing, inland.

Description: Most probable gear used by each fisher. Terminology is mostly inspired by codes used in the European Data Collection Framework (https://dcf.ec.europa.eu/data-calls/definitions-and-terminology/g/gear_en). Otm is pelagic (midwater) otter-trawl; gns_spf is gillnets targeting small pelagic fish; gns_fws is gillnets targeting freshwater species; fpn_ana is traps (or pots) targeting anadromous species; lhp is Handlines and pole-lines (hand-operated); icefishing is fishing with lines by carving holes on iced surfaces of coastal areas and lakes; inland is a general description for any fishing activity performed in lakes and rivers.

Method: Case C4. In the case when the strategy is cope or react, the CPT reflects literature as described in Annex C. When the strategy is React, it is assigned expert based probability based on interviews interpretation.

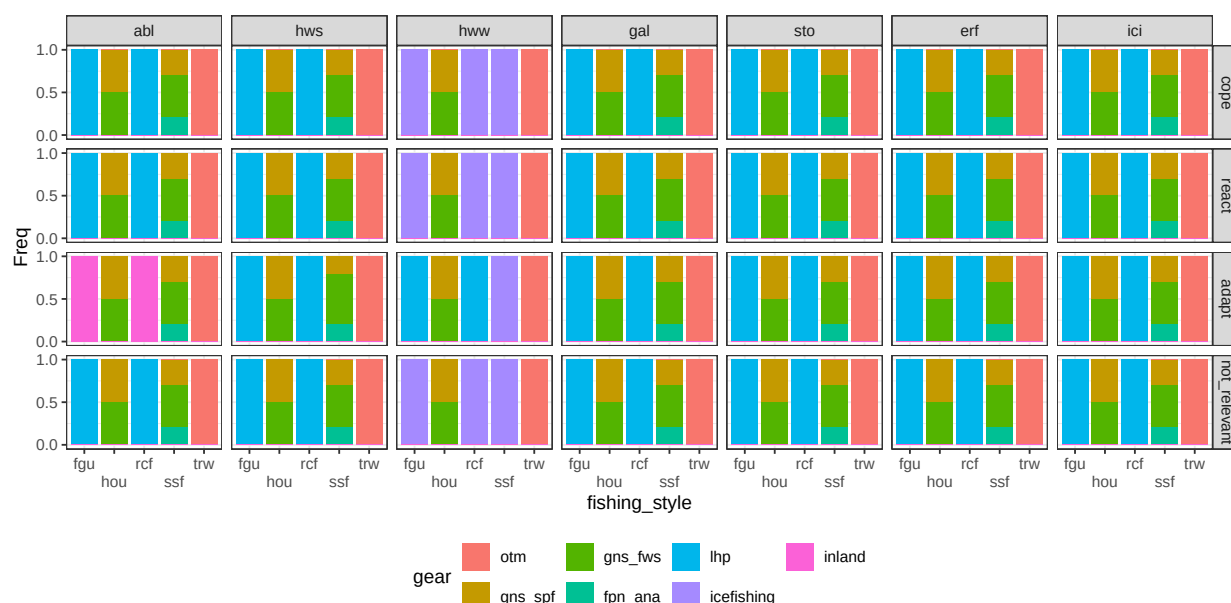

Figure S.17: conditional distribution for gear. Columns represents levels of the node extreme_event; rows are levels of the node strategy_to_change.

Catchability

Parents: target, extreme_event, gear.

Levels: worse, same, better.

Description: The ability to catch fish depending on gear-fish interactions. For example, a gillnet clogged in algae is more visible and less efficient (less catchability).

Method: Case C3 based on question Q 3.

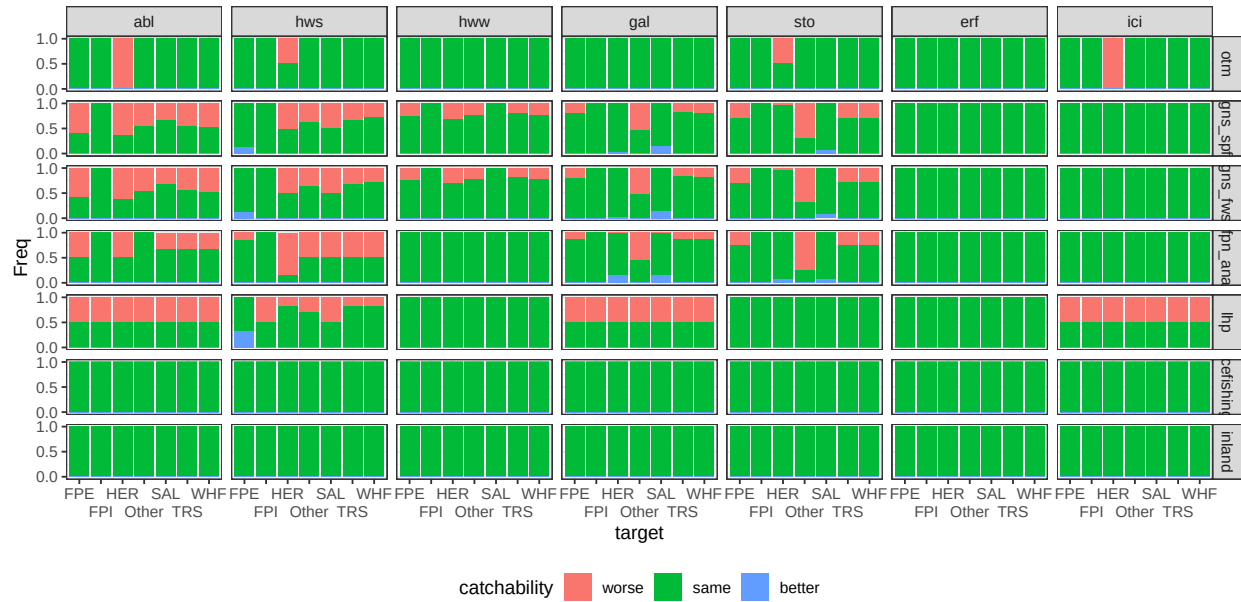

Figure S.18: conditional distribution for catchability. Columns represents levels of the node extreme_event; rows are levels of the node gear.

Catch condition

Parents: target, extreme_event, additional_mitigation.

Levels: worse, same.

Description: The real or perceived quality of catches in terms of aspect/health status. Does NOT refer to species composition or distribution. There are some “technical solutions” that balance for negative effects of MEW.

Method: Case C3 based on question Q5. The CPT is changed to 100% probability of level *same* when appropriate technical solutions (i.e.: travel further, ice machine) are mentioned in the narrative.

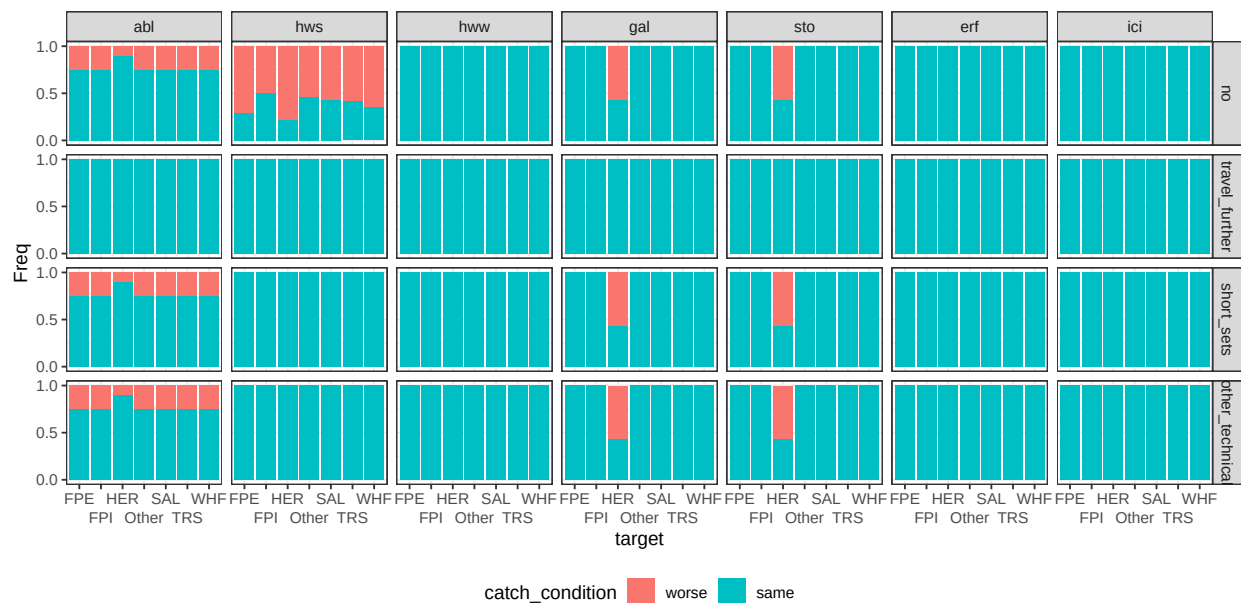

Figure S.19: conditional distribution for `catch_condition`. Columns represents levels of the node `extreme_event`; rows are levels of the node `additional_mitigation`.

Personal safety

Parents: extreme_event, gear, additional_mitigation.

Levels: no, minor, major.

Description: Any variation to ordinary working conditions that can increase the potential physical damage for operators (i.e.: slipping; a violent storm is life threatening). There are some “technical solutions” that balance for negative effects of MEW.

Method: Case C3 based on question Q9. The CPT is changed to 100% probability of level *no* when appropriate technical solutions (i.e.: travel further) are mentioned in the narrative.

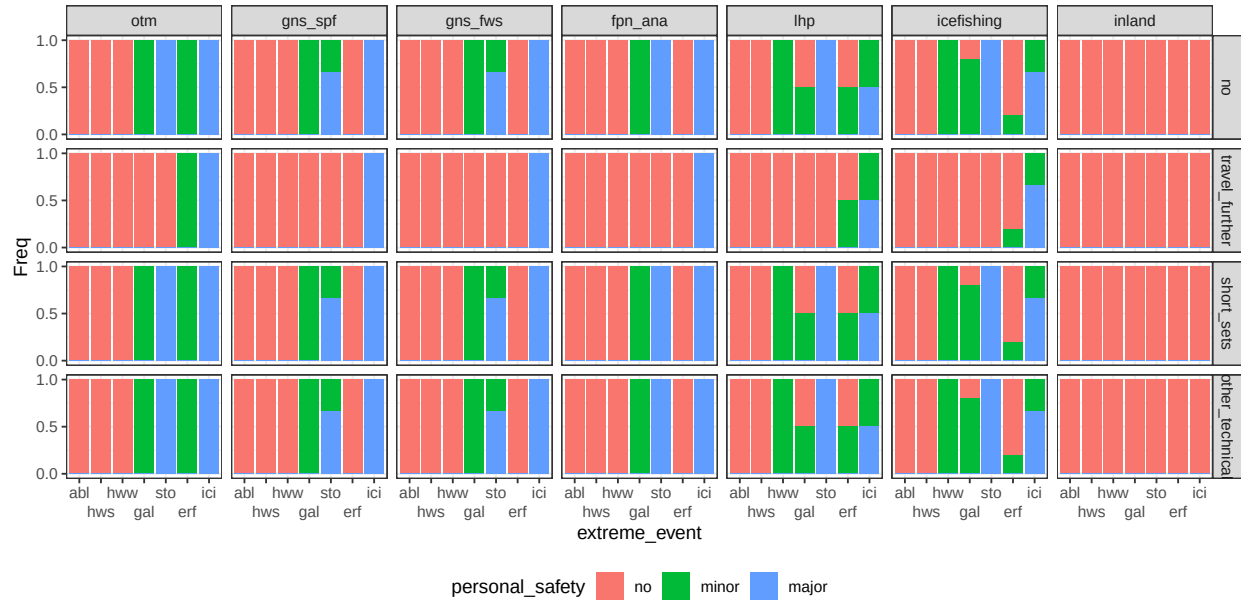

Figure S.20: conditional distribution for *personal_safety*. Columns represents levels of the node *gear*; rows are levels of the node *additional_mitigation*.

Damage

Parents: extreme_event, gear, additional_mitigation.

Levels: no, minor, major, destroy.

Description: Damage to the fishing gear ranging from minor to completely losing the fishing gear or part of it because it was lost or irreparably damaged. There are some “technical solutions” that balance for negative effects of MEW.

Method: Case C3 based on question Q10. The CPT is changed to 100% probability of level *no* when appropriate technical solutions (i.e.: travel further) are mentioned in the narrative.

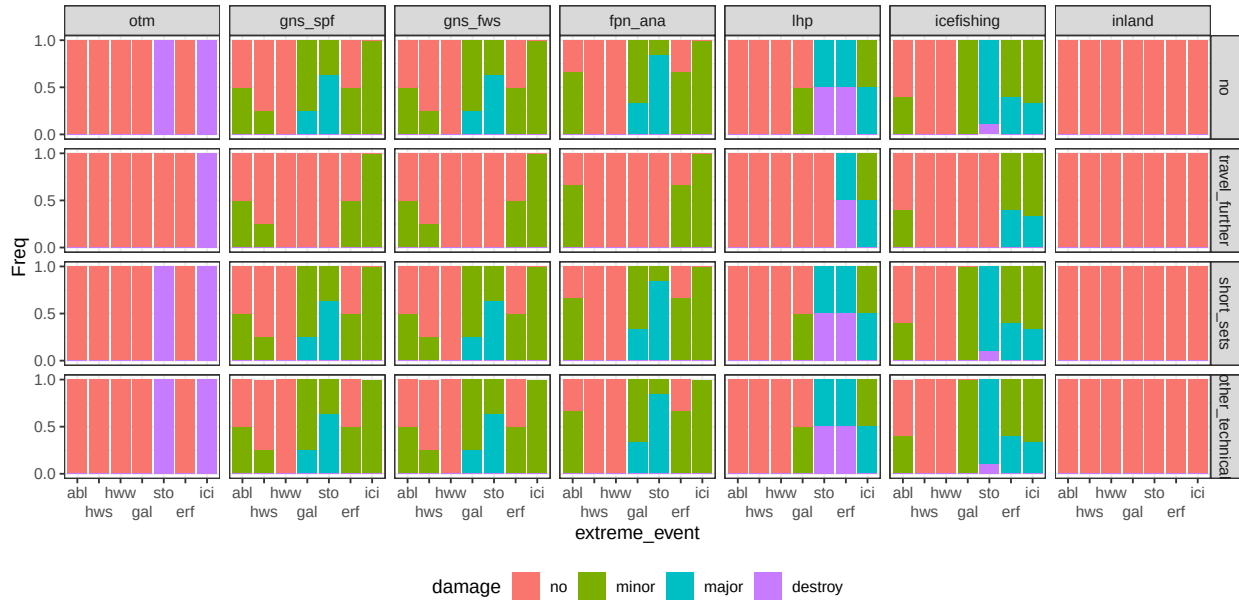

Figure S.21: conditional distribution for damage. Columns represents levels of the node gear; rows are levels of the node additional_mitigation.

Target

Parents: gear, strategy_to_change, extreme_event.

Levels: herring, perch, pike, salmon, sea_trout, whitefish, not_specified.

Description: The most probable target species associated to each fishing gear. The levels describe the 5 most common species that are relevant across the fishing styles, one aggregation for whitefish (including Common whitefish and vendace), and one category to group any other species. The category not_specified is also assigned to inland and not relevant.

Method: Case C4. In the case when the strategy is cope or react, the CPT reflects literature as described in Annex C. When the strategy is React, it is assigned expert based probability based on interviews interpretation.

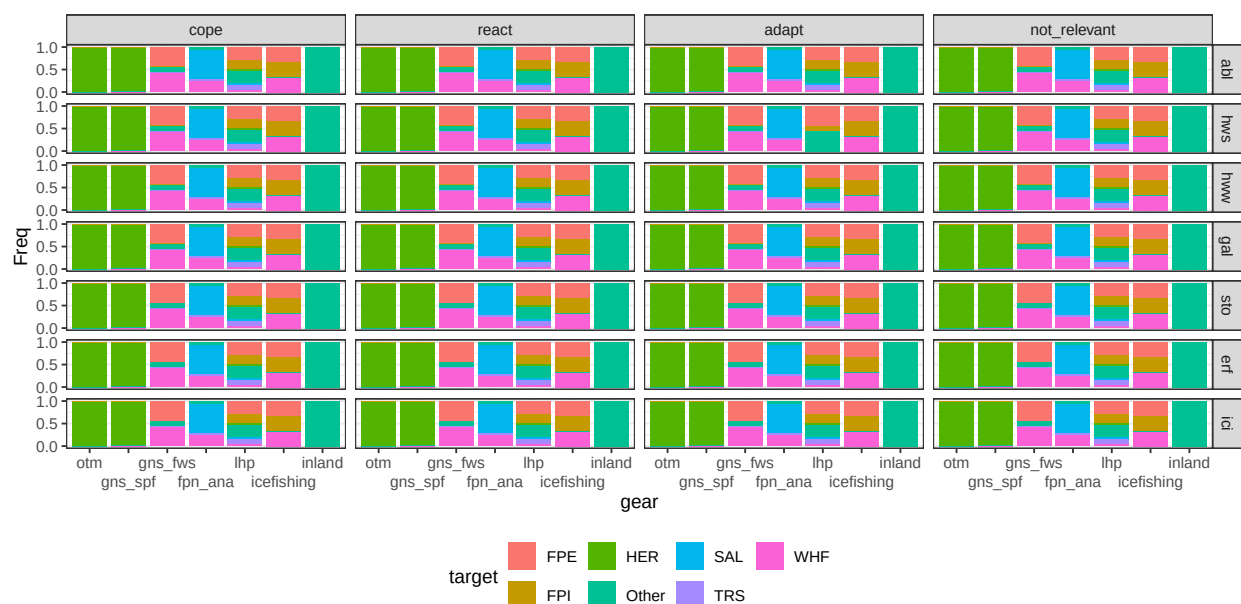

Figure S.22: conditional distribution for target. Columns represents levels of the node strategy_to_change; rows are levels of the node extreme_event.

Go fishing

Parents: extreme_event, fishing_style, strategy_to_change, aware_of_event.

Levels: no, yes.

Description: The probability to go out fishing.

Method: Case C3 based on question Q2 when the level of the parent node strategy is *cope*. The CPT is changed to 100% probability of level *yes* when parent node strategy is *adapt* or *react*.

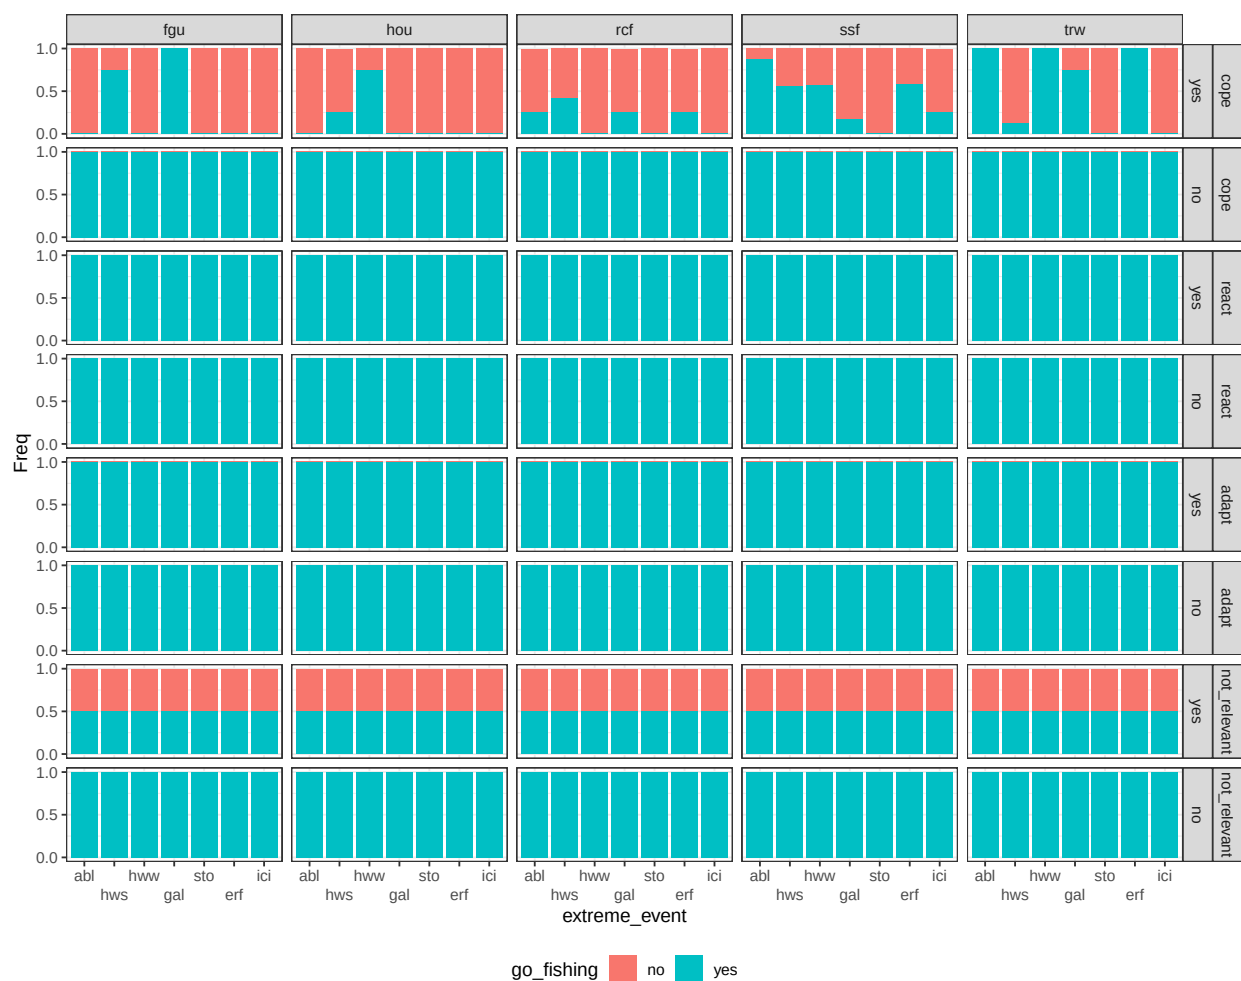

Figure S.23: conditional distribution for *go_fishing*. Columns represents levels of the node *fishing_style*; rows are combinations levels of the nodes *strategy_to_change* and *aware_of_event*.

Chance nodes - User

Stress

Parents: personal_safety, damage, catch_condition, fishing_style.

Levels: no, yes.

Description: Psychological aspect, elements such as anxiety and sense of fatigue (Chatterjee and and Bolar, 2019). The stressful events considered are having damages to the gear, being injured, being the catch in poor condition.

Method: Case C2. Weight based on questions Q21 a, b and c. Algorithm is wmin.

Figure S.24: conditional distribution for stress. Columns represents levels of the node damage; rows are combinations levels of the nodes catch_condition and fishing_style.

Health

Parents: stress, personal_safety.

Levels: low, medium, high.

Description: Summarizes variables related to physical and mental health. The wmin algorithm implies that all the conditions are necessary to obtain a large value, however the physical injuries are more relevant than stress.

Method: Case C2. Weight ratio for the parent *stress* and *personal safety* is 1:3. Algorithm is wmin.

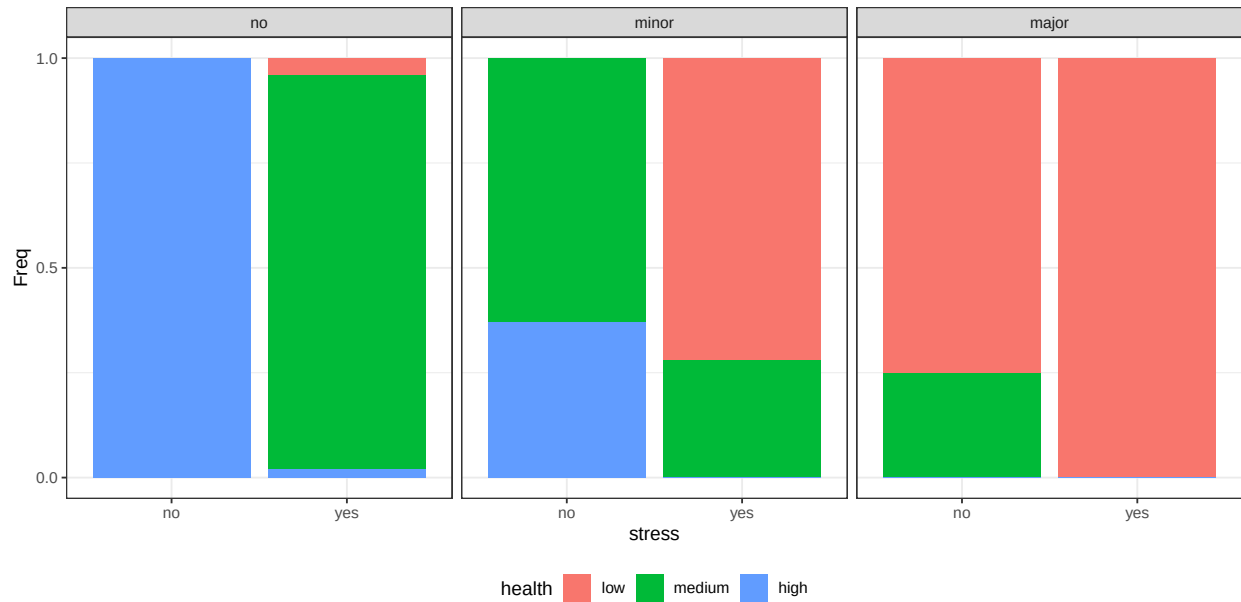

Figure S.25: conditional distribution for health. Columns represents levels of the node personal_safety.

Satisfaction

Parents: catches, catch_condition.

Levels: low, medium, high.

Description: Summarizes variables related to the quality and amount of catches. The wmin algorithm implies that all the conditions are necessary to obtain a large value.

Method: Case C2 with equal weight. Algorithm is wmin.

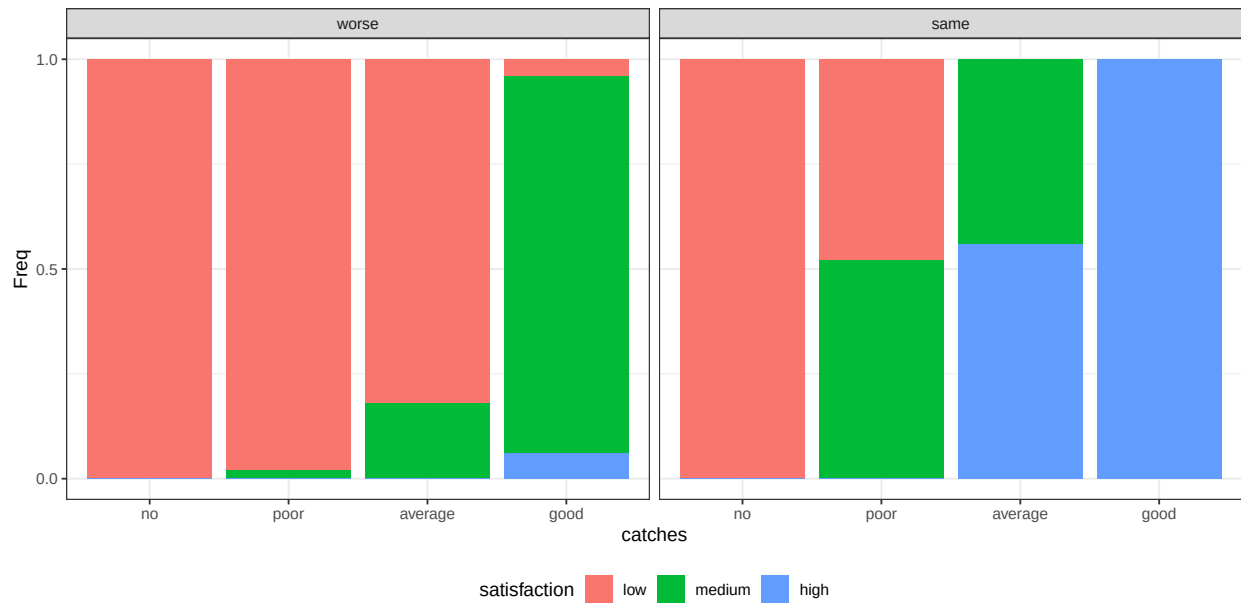

Figure S.26: conditional distribution for satisfaction. Columns represents levels of the node catch_condition.

Substitution capacity

Parents: fishing_style.

Levels: no, yes.

Description: The impact of a lost day is not determined by the loss itself, but by its recoverability. When value is tied to outcomes, time can be lost and later absorbed. When value is tied to time itself, loss becomes irreversible.

Method: Case C1 based on extra question.

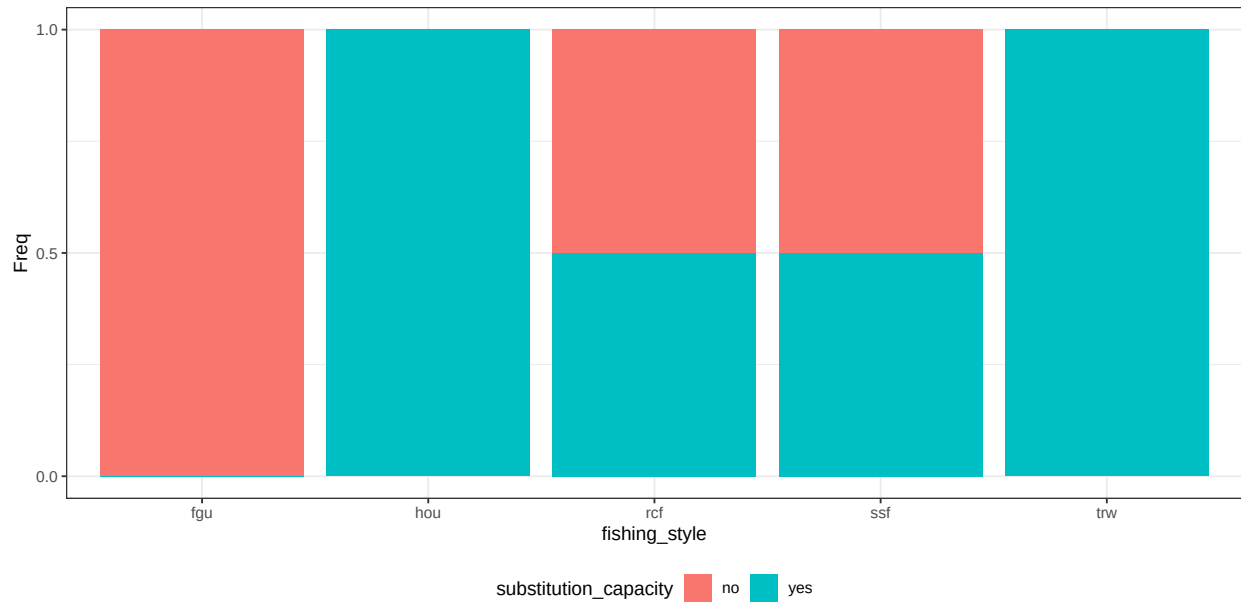

Figure S.27: conditional distribution for substitution_capacity.

Non monetary_value

Parents: health, satisfaction, substitution_capacity, go_fishing.

Levels: low, medium, high.

Description: Summarizes the non-monetary outcomes associated to the fishing experience. It depends on the possibility to go out fishing and to obtain satisfying catches, while staying safe. The wmin algorithm implies that all the conditions are necessary to obtain a large value.

Method: Case C2 with equal weight. Algorithm is wmin.

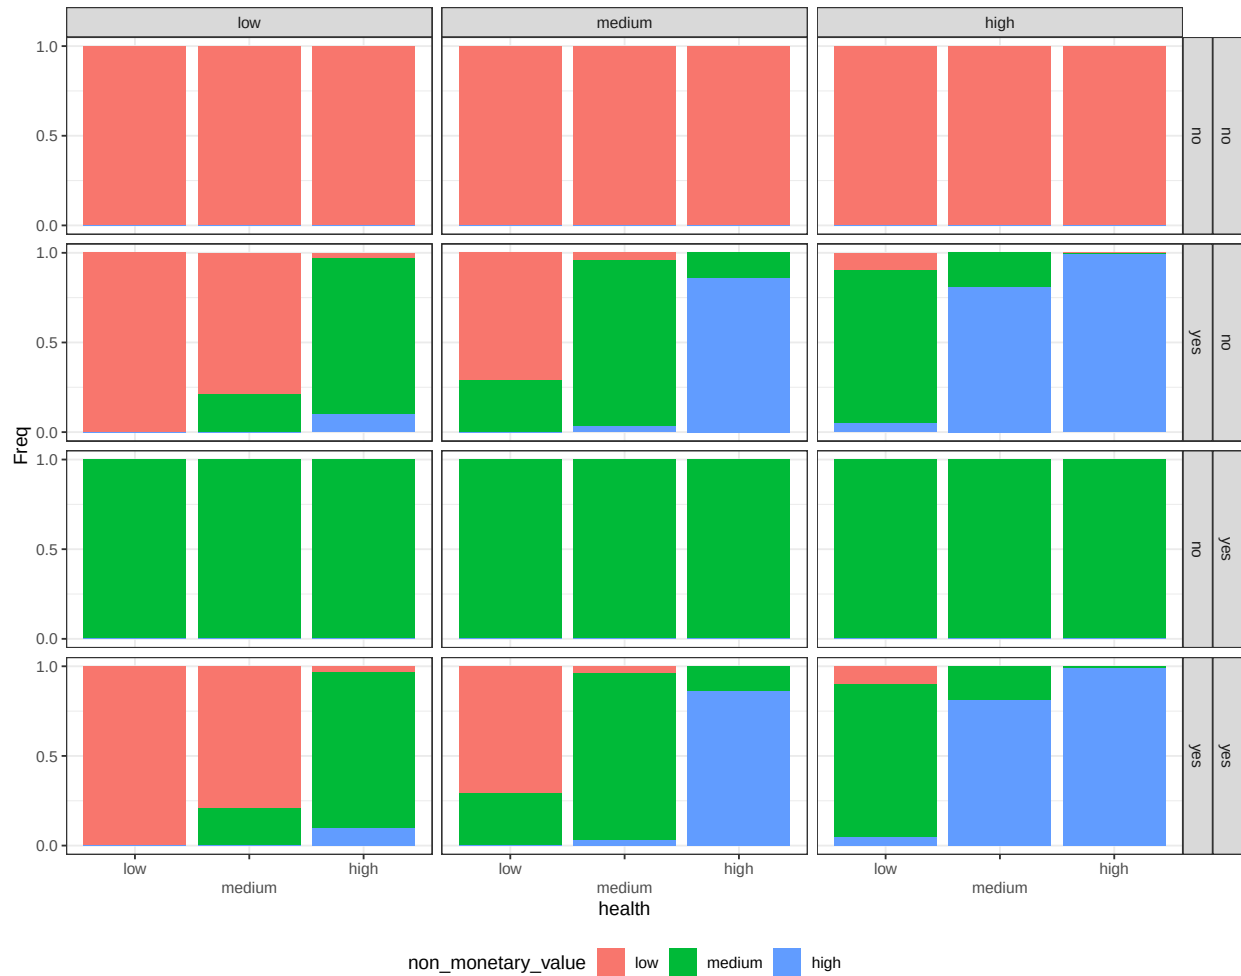

Figure S.28: conditional distribution for non_monetary_value. Columns represents levels of the node satisfaction; rows are combinations levels of the nodes substitution_capacity and go_fishing.

Chance nodes - Economic

Costs

Parents: additional_mitigation, damage, fishing_style.

Levels: no, low, medium, high.

Description: Represent how large is the costs associated with an extreme weather event compared to the annual expected costs. No is $< 0.5\%$; Low is between 0.5% and 2.5% ; Medium is between 2.5% and 5% ; high is larger than 5% .

Method: Case C4. The CPT reflects literature and interviews as described in Annex C..

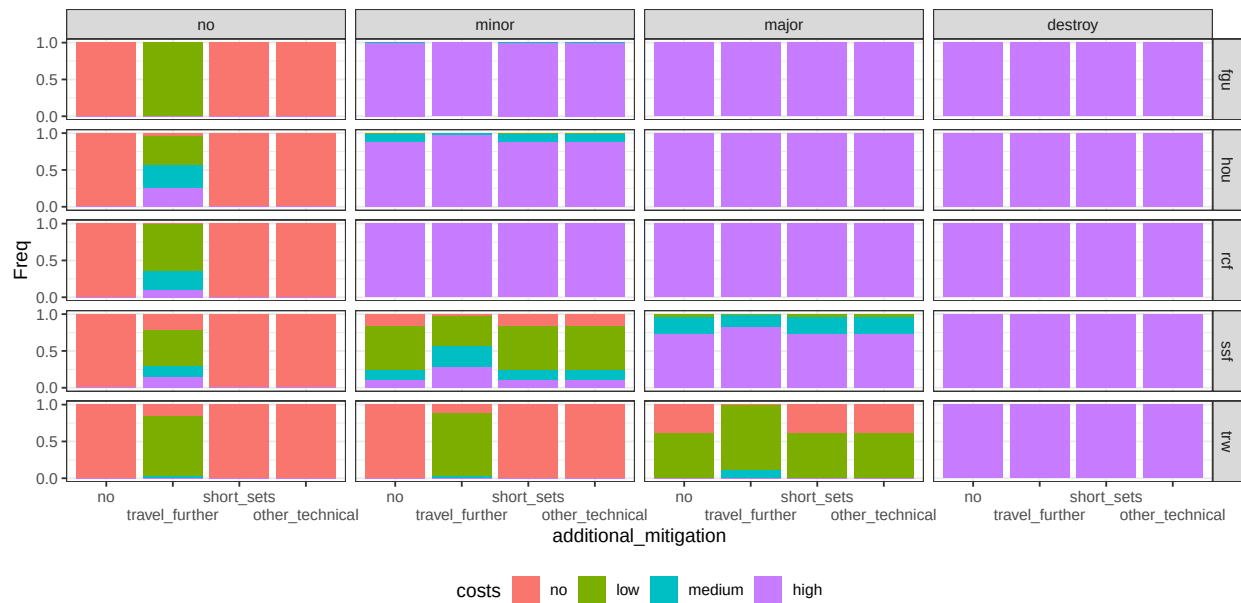

Figure S.29: conditional distribution for costs. Columns represents levels of the node damage; rows are levels of the node fishing_style.

Monetary loss

Parents: substitution_capacity, costs, fishing_style, go_fishing.

Levels: no, low, medium, high.

Description: NA.

Method: Case C3. In the case of recreational fishers, if the node go_out is no then the cost is no. For commercial fishers, if the node go_out is no the cost depend on the estimated cost of a missed fishing day balanced on objectives type. When the node go out is yes, loss equal costs.

Figure S.30: conditional distribution for monetary_loss. Columns represents levels of the node costs; rows are combinations levels of the nodes fishing_style and go_fishing.

Credit

Parents: fishing_style.

Levels: difficult, neutral, easy.

Description: The possibility to obtain loans for investments.

Method: Case C1 based on question Q 25.

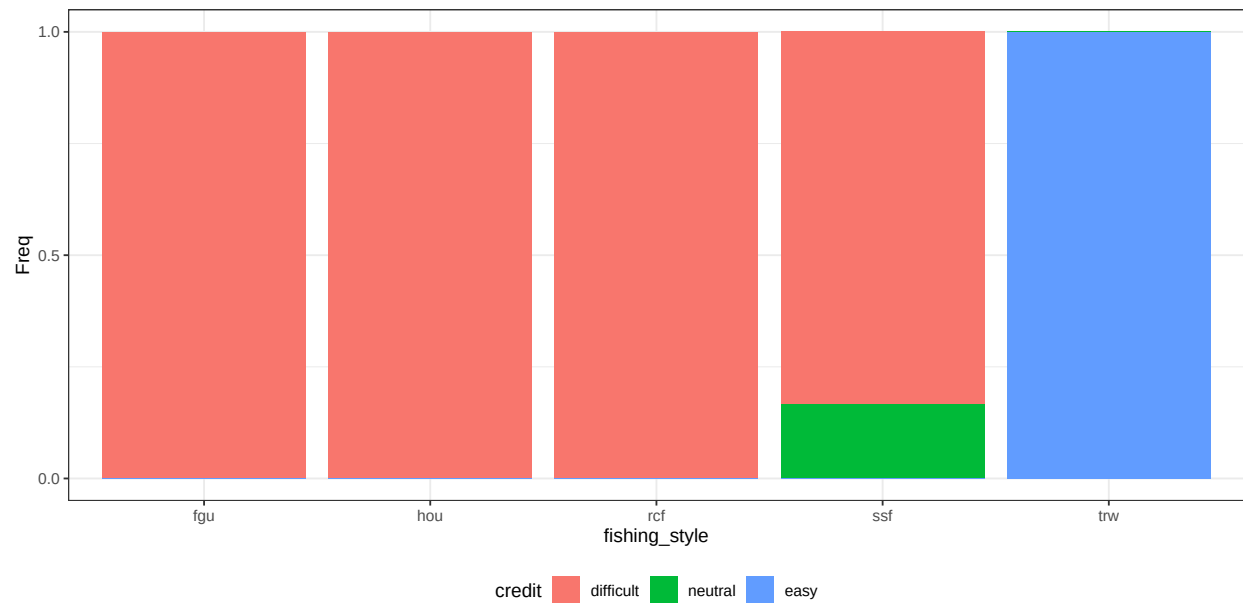

Figure S.31: conditional distribution for credit.

Job mobility

Parents: fishing_style.

Levels: low, medium, high.

Description: The extent to which non-fishing income-generating activities are accessible to an individual or household.

Method: Case C1 based on question Q 23.

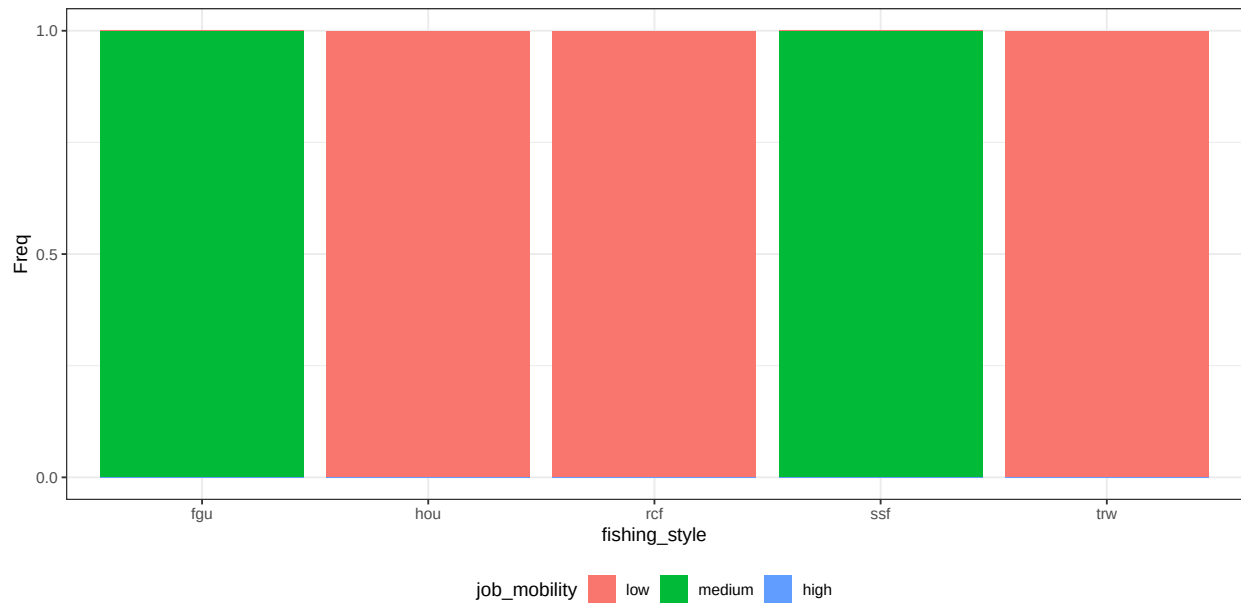

Figure S.32: conditional distribution for job_mobility.

Economic buffers

Parents: job_mobility, credit.

Levels: low, medium, high.

Description: Describes the capability to buffer economic loss by obtaining credits or by replacing with other jobs. Only professionals are capable to obtain economic buffers.

Method: Case C2 with unequal weight, job mobility is 50% less important than credit. Algorithm is wmax.

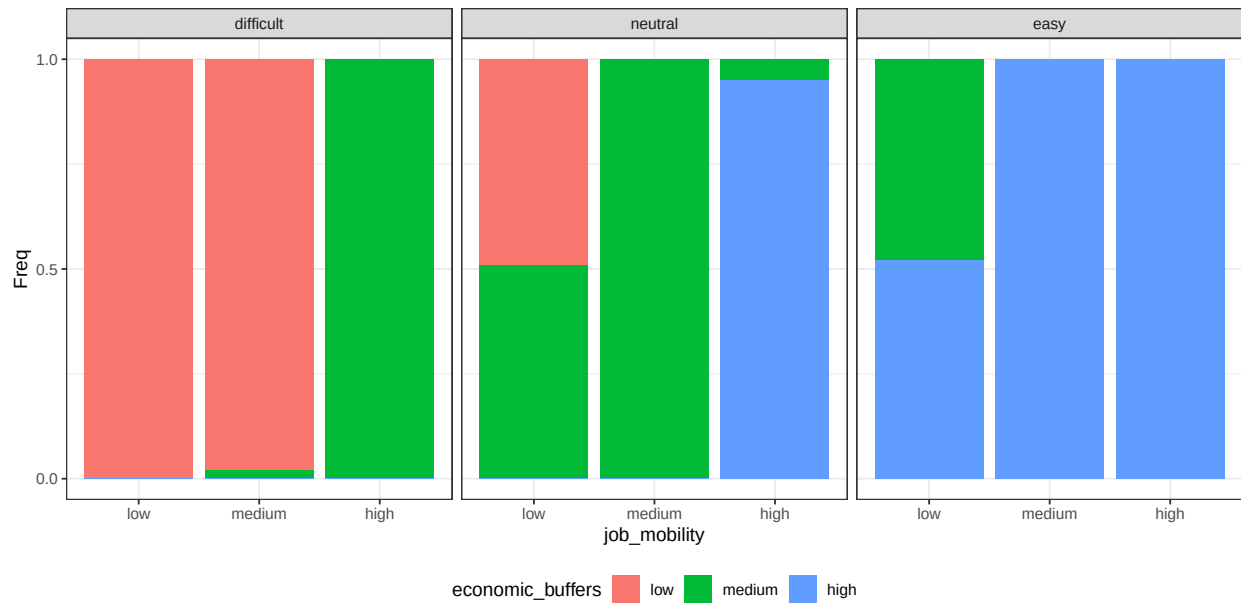

Figure S.33: conditional distribution for economic_buffers. Columns represents levels of the node credit.

Next figure represent the conditional probability distribution of the node economic buffers by fishing style

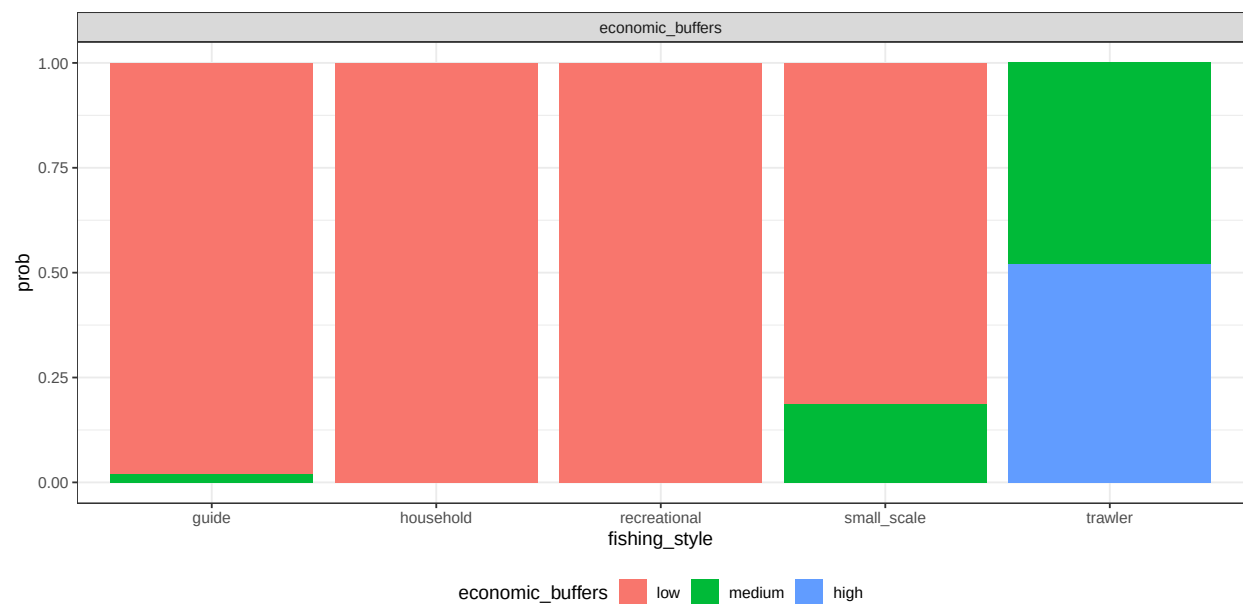

Figure S.34: conditional probability distribution of the node individual importance by fishing style

Chance nodes - Individual

Identity

Parents: fishing_style.

Levels: not_important, somehow_important, very_important.

Description: The degree to which fishing contributes to an individual's sense of identity, including self-perception.

Method: Case C1 based on question Q 33.

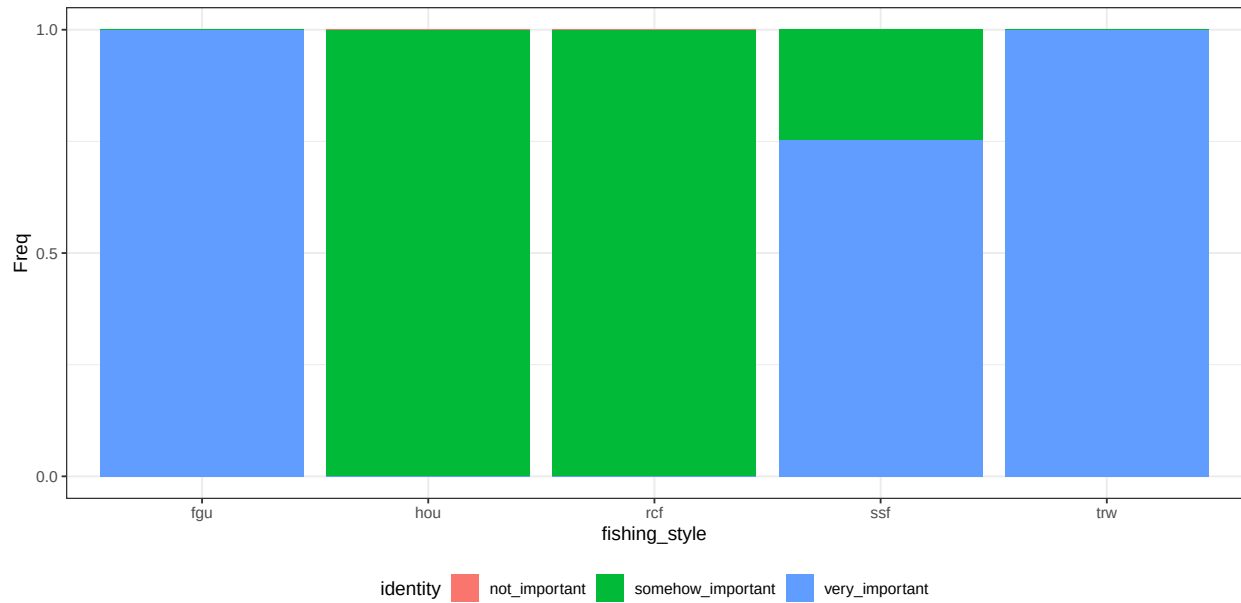

Figure S.35: conditional distribution for identity.

Sense of_home

Parents: fishing_style.

Levels: not_important, somehow_important, very_important.

Description: The degree to which fishing contributes to build a sense of place/home to a specific location. It can either be at sea or at land.

Method: Case C1 based on question Q 34.

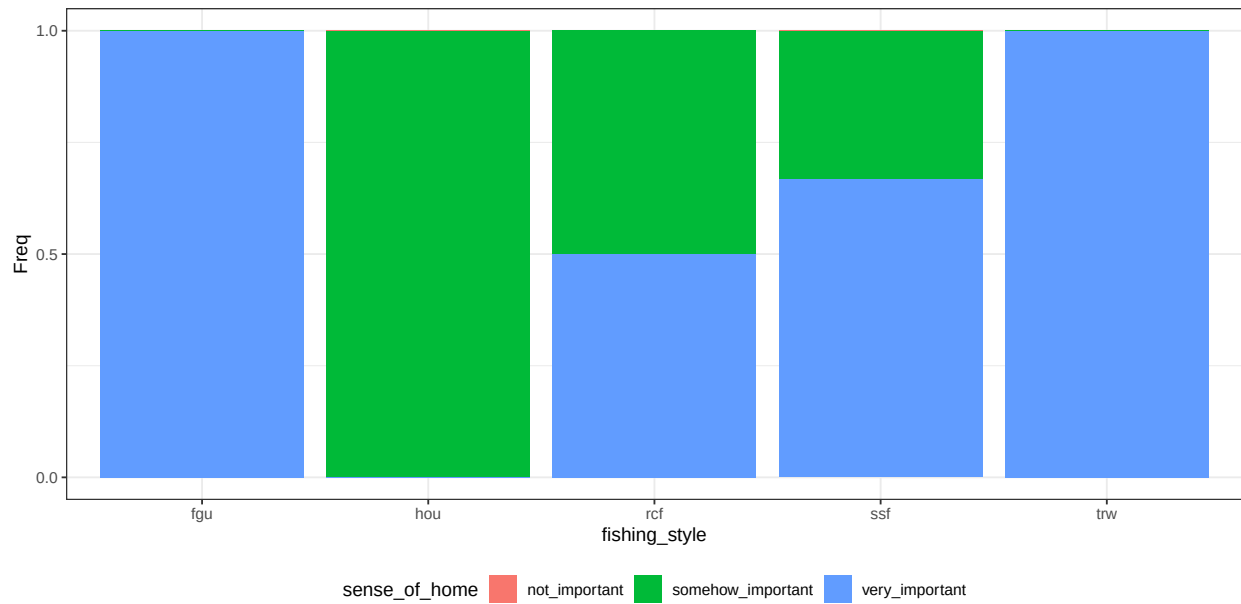

Figure S.36: conditional distribution for sense_of_home.

Outdoor benefit

Parents: fishing_style.

Levels: not_important, somehow_important, very_important.

Description: The extent which an individual value the time spent outdoor (while fishing) to his personal well-being.

Method: Case C1 based on question Q 32.

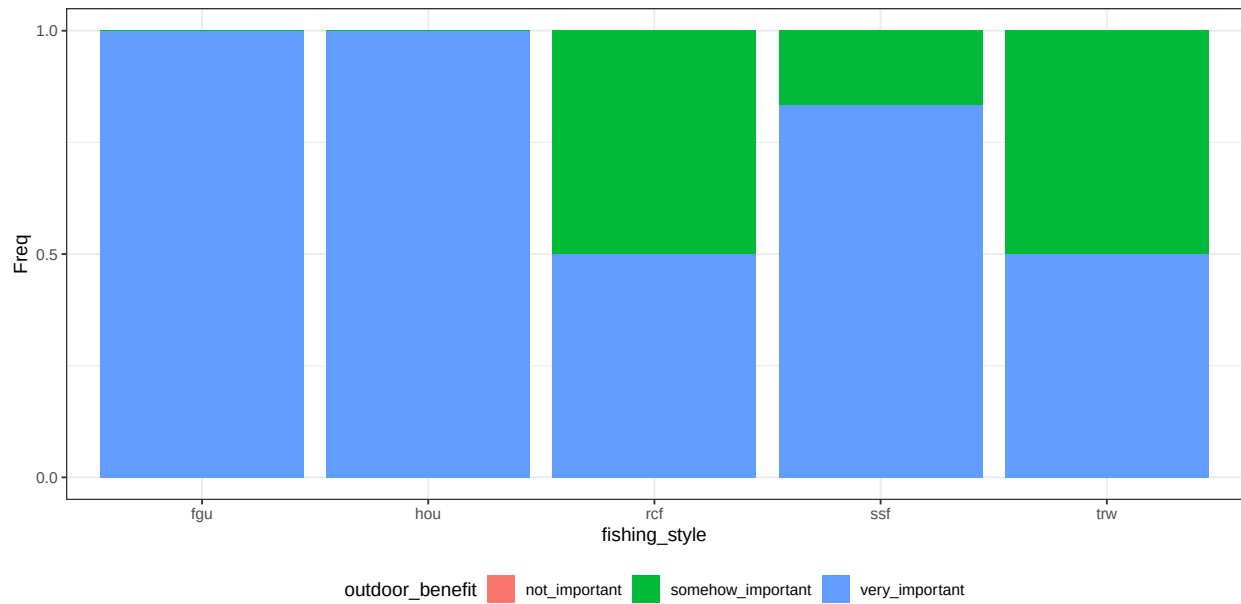

Figure S.37: conditional distribution for outdoor_benefit.

Individual importance

Parents: outdoor_benefit, identity, sense_of_home.

Levels: low, medium, high.

Description: Summarizes the importance of the variables defining individual features to different fishers. The algorithm wmax gives more contribution to large states.

Method: Case C2 with equal weight. Algorithm is wmax.

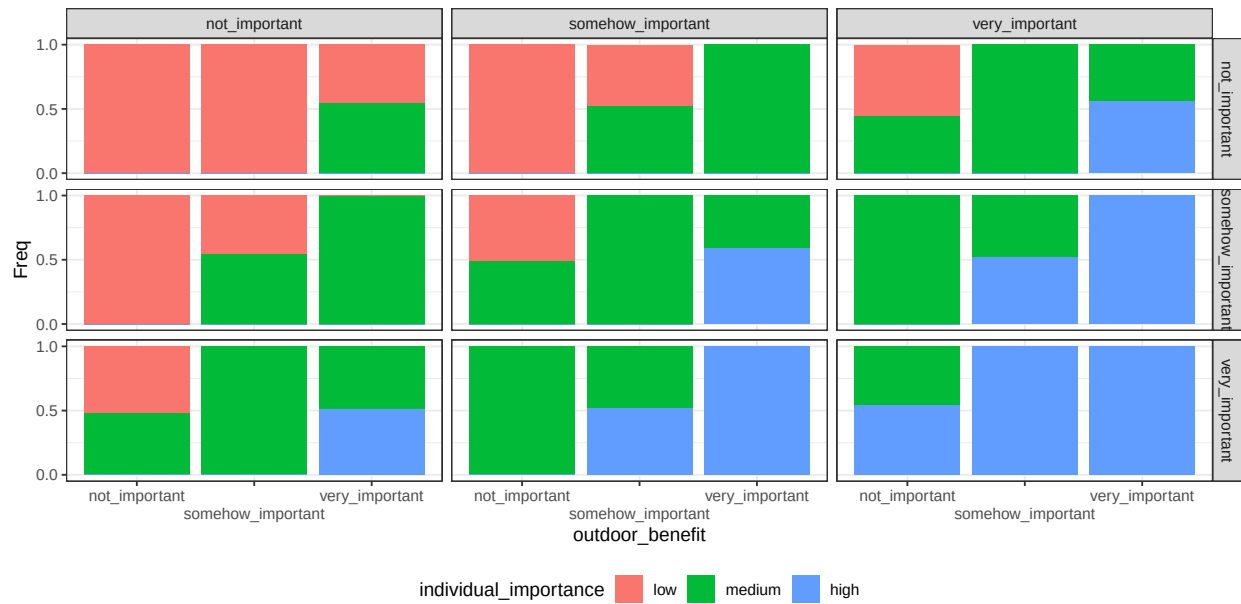

Figure S.38: conditional distribution for `individual_importance`. Columns represents levels of the node `identity`; rows are levels of the node `sense_of_home`.

Next figure represent the conditional probability distribution of the node individual importance by fishing style

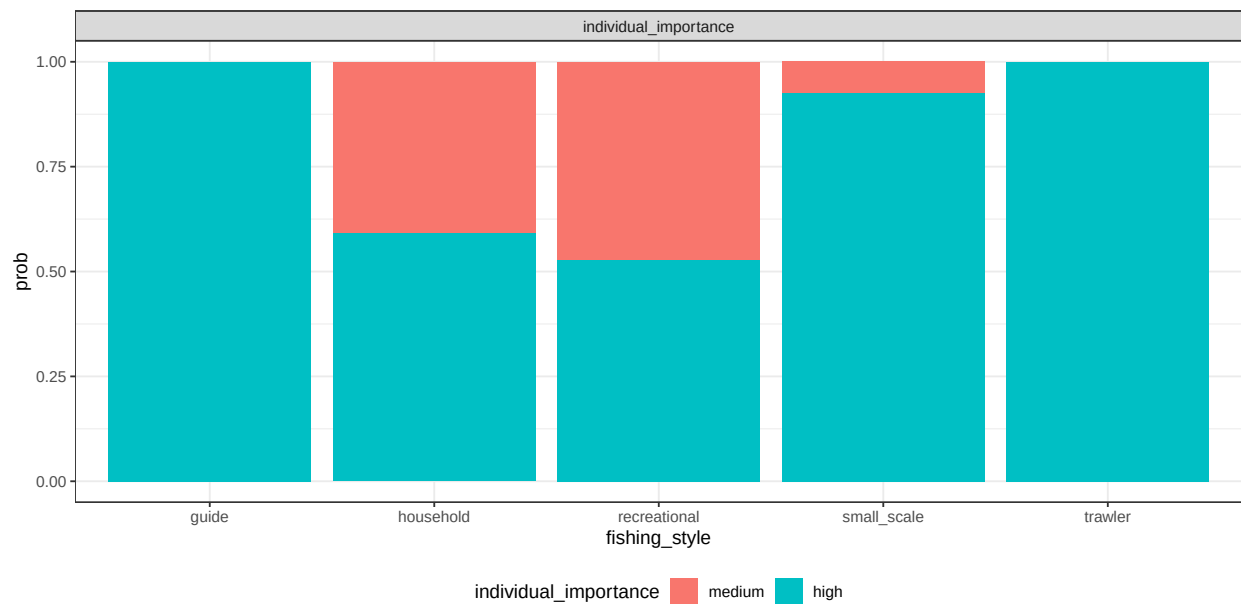

Figure S.39: conditional probability distribution of the node individual importance by fishing style

Chance nodes - Societal

Knowledge transmission

Parents: fishing_style.

Levels: not_important, somehow_important, very_important.

Description: The extent which an individual value the transmission of fishing knowledge and culture to future generations.

Method: Case C1 based on question Q 27.

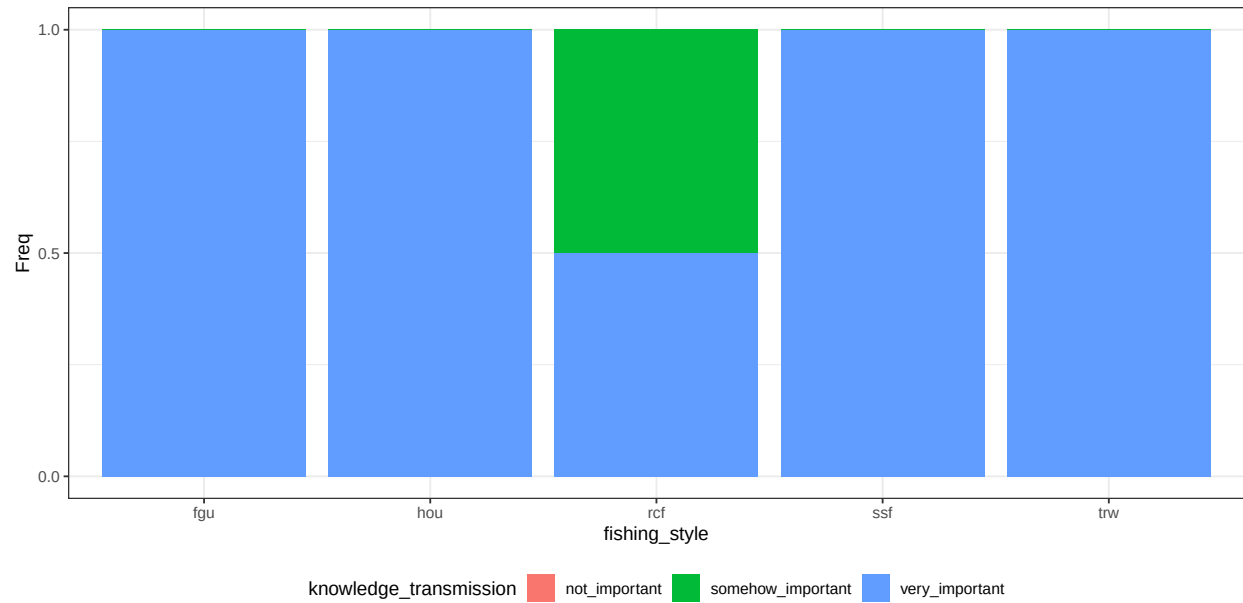

Figure S.40: conditional distribution for knowledge_transmission.

Benefit local_community

Parents: fishing_style.

Levels: not_important, somehow_important, very_important.

Description: The extent which an individual value fishing to build/maintain social relations within an extended local community, such as a town or neighborhood.

Method: Case C1 based on question Q 28.

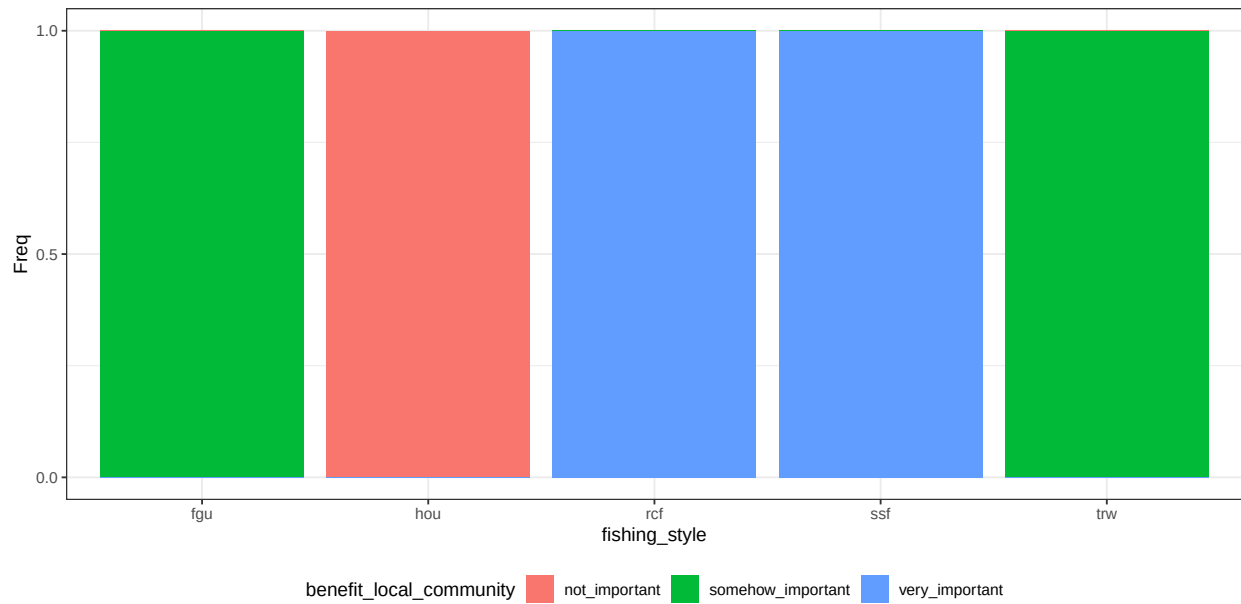

Figure S.41: conditional distribution for benefit_local_community.

Traditional food

Parents: fishing_style.

Levels: not_important, somehow_important, very_important.

Description: The extent which fishing contributes to provide for traditional food.

Method: Case C1 based on question Q 30.

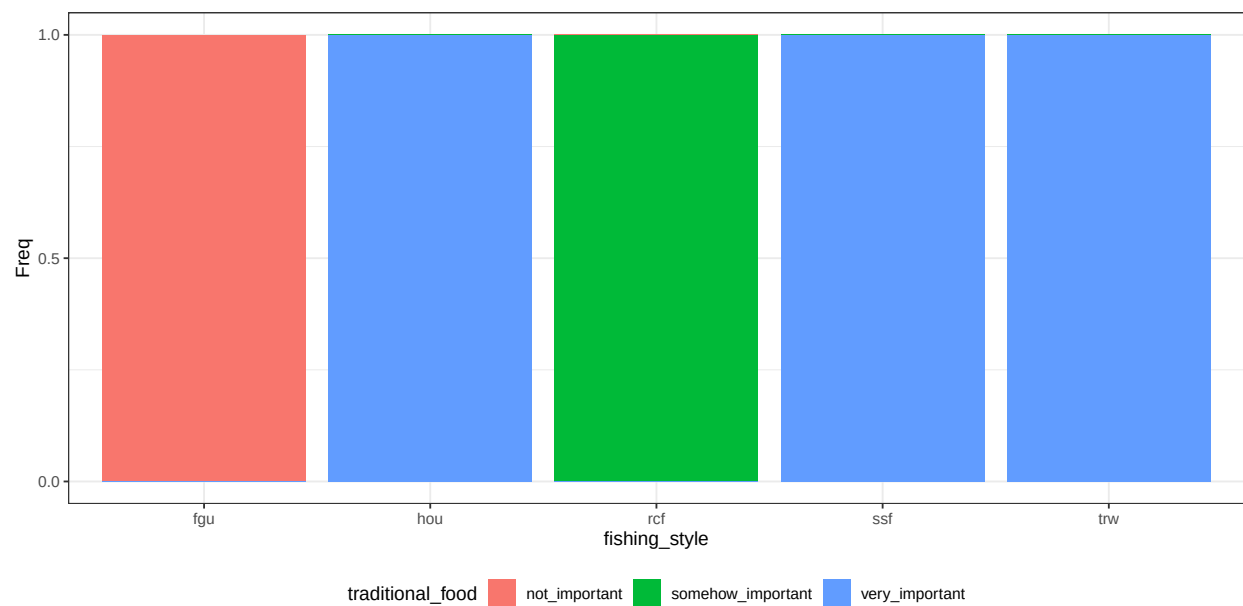

Figure S.42: conditional distribution for traditional_food.

Benefit personal_community

Parents: fishing_style.

Levels: not_important, somehow_important, very_important.

Description: The extent which an individual value fishing to build/maintain social relations within a small community, such as groups of friends or associations.

Method: Case C1 based on question Q 29.

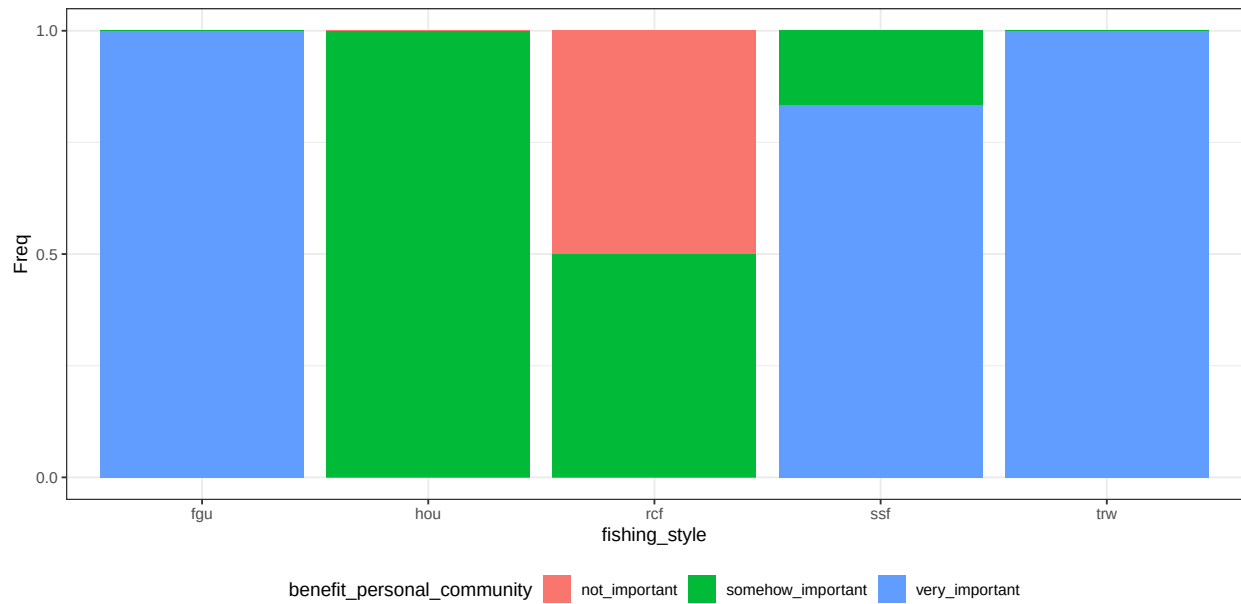

Figure S.43: conditional distribution for benefit_personal_community.

Societal importance

Parents: knowledge_transmission, benefit_local_community, traditional_food, benefit_personal_community.

Levels: low, medium, high.

Description: Summarizes the importance of the variables defining societal features to different fishers. The algorithm wmax gives more contribution to large states.

Method: Case C2 with equal weight. Algorithm is wmax.

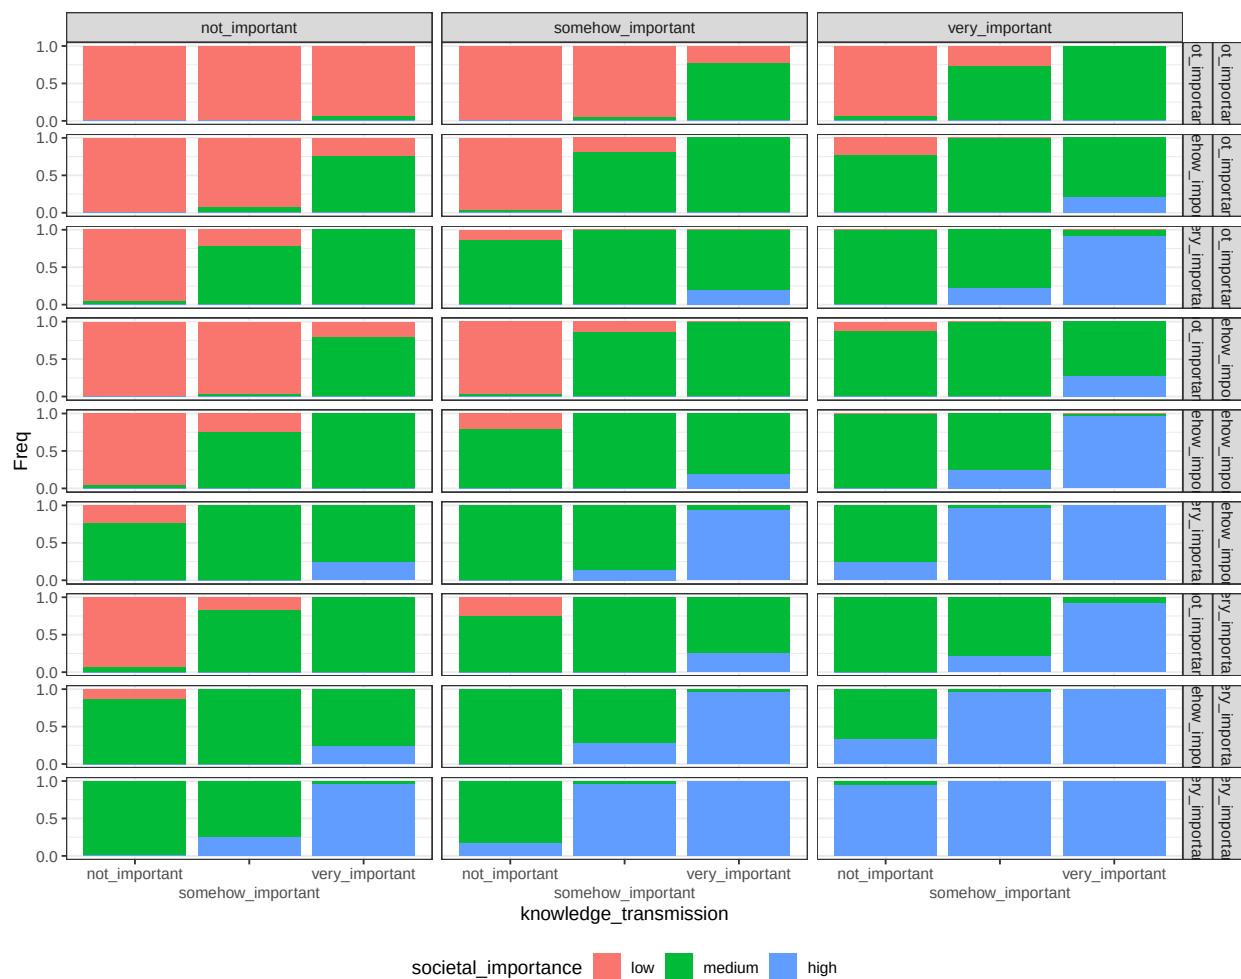

Figure S.44: conditional distribution for societal_importance. Columns represents levels of the node benefit_local_community; rows are combinations levels of the nodes traditional_food and benefit_personal_community.

Next figure represent the conditional probability distribution of the node societal importance by fishing style

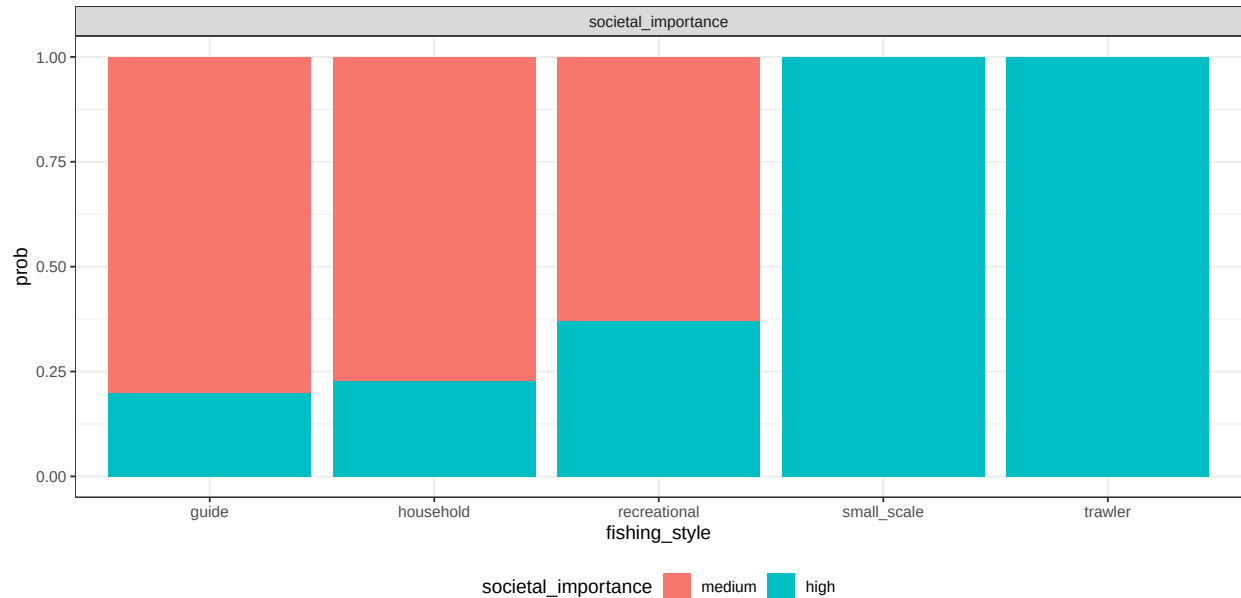

Figure S.45: conditional probability distribution of the node individual importance by fishing style

Risk

Shape how different fisheries will perceive risk. To each of these variables, the effect of the human community variables is to be interpreted as “how much this variable is important”? The CPT table combine the concepts of ranked nodes and the classic definition of $\text{Risk} = \text{Hazard} * \text{Vulnerability}$. In the case of individual and societal importance, Risk is exactly calculated as $\text{Hazard} * \text{Vulnerability}$. Parent categories (Low, medium and high; as well as not important, somehow important and very important) are mapped to 0, 0.5 and 1 values. The parent value are multiplied.

Individual risk

Parents: individual_importance, non_monetary_value, strategy_to_change.

Levels: low, medium, high, not_relevant.

Description: The risk of having a mismatch between the outcomes that fishing provides and the importance that individual well-being receives from fishing.

Method: Case C5.

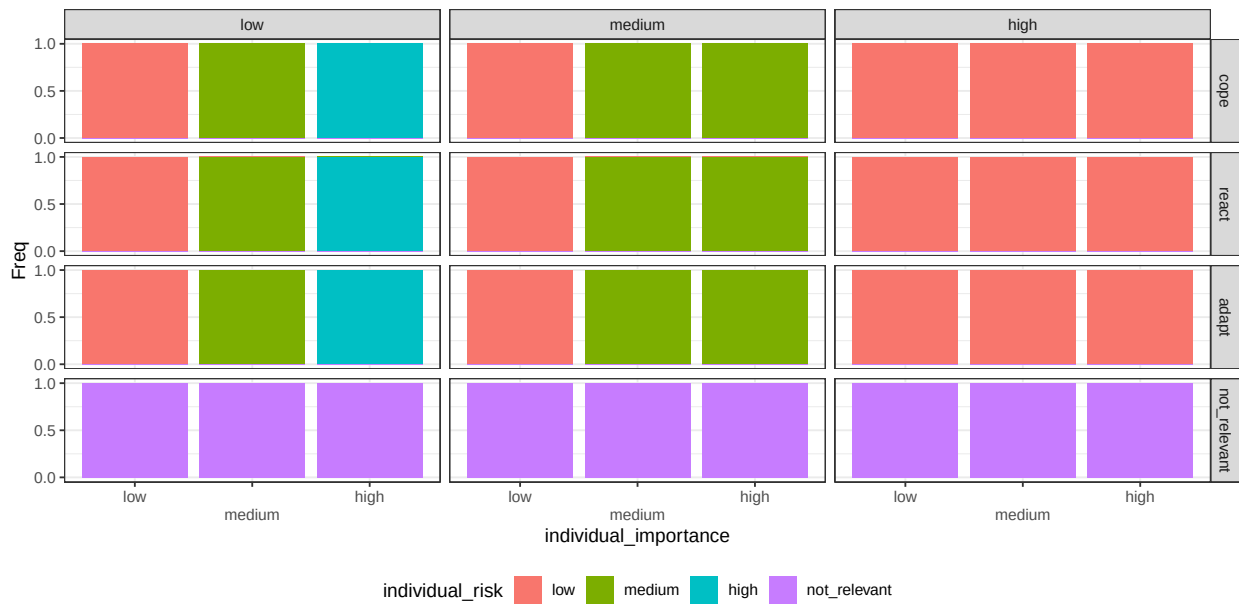

Figure S.46: conditional distribution for individual_risk. Columns represents levels of the node non_monetary_value; rows are levels of the node strategy_to_change.

Societal risk

Parents: societal_importance, non_monetary_value, strategy_to_change.

Levels: low, medium, high, not_relevant.

Description: The risk of having a mismatch between the outcomes that fishing provides and the importance that fishing provides to society.

Method: Case C5.

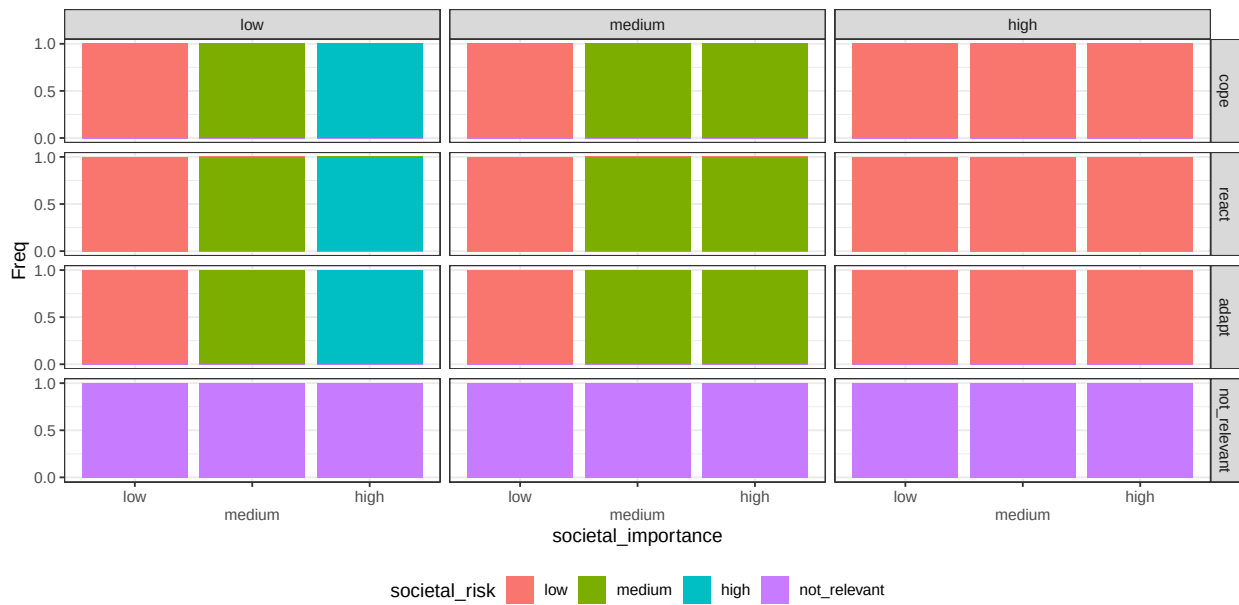

Figure S.47: conditional distribution for societal_risk. Columns represents levels of the node non_monetary_value; rows are levels of the node strategy_to_change.

Economic risk

Parents: economic_buffers, monetary_loss, strategy_to_change.

Levels: low, medium, high, not_relevant.

Description: The risk of having economic fluctuations balanced for how economy is considered an important value.

Method: Case C2. Weight ratio for the parent *importance* and *cost* is 1:2. Algorithm is wmax.

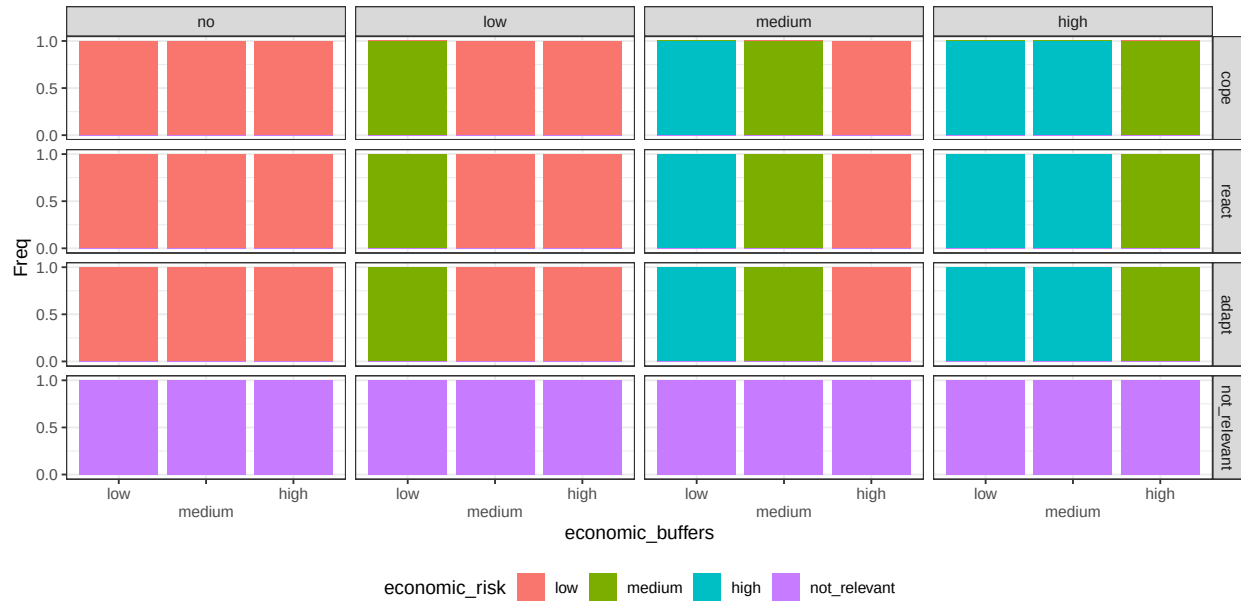

Figure S.48: conditional distribution for *economic_risk*. Columns represents levels of the node *monetary_loss*; rows are levels of the node *strategy_to_change*.
